ACKNOWLEDGMENTS

I would like to thank my dissertation advisor, Dr. Bingtuan Li, for his guidance, patience, encouragement and leadership. It has been a precious experience to collaborate with him and have him as a mentor. I thank my committee members for their support and encouragement throughout.

I wish to thank my family for providing me with unconditional love and unsurpassed support no matter where we are. In particular, I thank my mom, Wenjie Wang, for her always being so supportive on not only my study but also my life and dream. I thank my dad, Yiming Wang, for showing me the way to pursue my goal with my passion and diligence. I thank my husband, Roger Ouch, for his patience, love, support and always believing in me.

ABSTRACT

A STAGE-STRUCTURED DELAYED REACTION-DIFFUSION MODEL FOR COMPETITION BETWEEN TWO SPECIES

Chunwei Wang

June 5, 2013

We formulate a delayed reaction-diffusion model that describes competition between two species in a stream. We divide each species into two compartments, individuals inhabiting on the benthos and individuals drifting in the stream. Time delays are incorporated to measure the time lengths from birth to maturity of the benthic populations. We assume that the growth of population takes place on the benthos and that dispersal occurs in the stream. Our system consists of two linear reaction-diffusion equations and two delayed ordinary differential equations. We study the dynamics of the non-spatial model, determine the existence and global stability of the equilibria, and provide conditions under which solutions converge to the equilibria. We show that the existence of traveling wave solutions can be established through compact integral operators. We define two real numbers and prove that they serve as the lower bounds of the speeds of traveling wave solutions in the system.

CHAPTER 1

INTRODUCTION AND BACKGROUND

1.1 Introduction

Many species, populations, communities, and ecosystems persist in environments where they spend some or all their life stages dispersing in media with strong directional bias. Typical examples include plants with windborn seeds, aquatic organisms in streams, and marine organisms with larval dispersal influenced by ocean currents. We focus on aquatic organisms living in streams, rivers, and estuaries which are characterized by unidirectional net water movement. Species living in such environments are facing the so-called “drift paradox” [1]. “Drift paradox” is one key issue for theory in stream ecology and states that extinction is inevitable in a closed population subjected only to downstream drift. We derive the ecological niche for persistence and spread of populations to avoid being swept downstream and out into habitats, where the physical or biotic environment is not conducive to their growth and reproduction.

Various hypotheses involving some compensatory upstream movement have been proposed as resolutions of the drift paradox. Müller [2, 3] claimed that adult insects balance out the downward drift of the insect larvae by flying upstream for oviposition. Waters [4] assumed that the drift paradox would be resolved if the species resided mainly on the benthos (the bottom of the stream) and only the surplus over the carrying capacity would drift in the stream. Persistence in

streams could also be affected by some movement mechanisms which include refugia in streams [5, 6, 7, 8, 9, 10] and variability effect in stream flow direction such as turbulence [38]. Speirs and Gurney [11, 12] stated that insect swimming in the water column and crawling on the benthos may permit the persistence of the population. They also pointed out that Water's hypothesis [4] neatly sidesteps the problem of how lotic species are able to sustain population losses due to drift, and implicit in their view is that drifting is merely a source of mortality. Experimental studies have been conducted to provide evidence both supporting [1, 4, 14] and contradicting [4, 15, 16] to the first hypothesis of upstream flight recolonization. However, adult flight patterns strongly depend on the species that we considered, and this hypothesis does not cover many important species often found in the drift that have no aerial phases. For the statement of insects swimming in the stream and crawling on the benthos, some experimental data were obtained [4, 17, 18, 19], but those experiments were not conducted for the purpose of solving the drift paradox.

Mathematical modeling studies have also been performed as the resolution of the drift paradox. Anholt [20] used a simulation model and argued that, instead of upstream-biased migration, density dependence was an essential factor in population persistence. (Density dependence: areas subjected to greater losses from the drift will experience a higher rate of population increase.) However, his simulation results overly emphasized the effect of density dependence for persistence and ignored the extinction that appeared in the simulations [11]. Humphries and Ruxton [12] changed the way of parameterizing of the principal in Anholt's model and showed that small-scale, random undirected movements on the streambed are enough to explain persistence of drifting organisms. Speirs and Gurney [11] focused on the role of diffusive dispersal as the balancing mechanism for the downstream drift and constructed a simplified one-dimensional model with diffusion.

Their model is given by

$$\frac{\partial n}{\partial t} = f(n)n - v \frac{\partial n}{\partial x} + D \frac{\partial^2 n}{\partial x^2}. \quad (1.1)$$

This model described a population residing in a stream, a river or an estuary subject to advection and diffusion. Here, $n(x, t)$ is the density of the population per unit area, $f(n)$ is the local per capita growth rate of the population, v is the advection velocity and D is the diffusion coefficient. The advection term represents downstream drift and the diffusive term represents random movement. They also applied the analytic results to four hydrodynamically disparate systems and demonstrated that upstream diffusive movement balanced out downstream flow for persistence.

The importance of involving diffusion is that random motion, due both to turbulent water movement and to randomly directed movements by individual organisms, is a key element in streams and rivers, and also a potential source of upstream recolonization.

Based on Speirs' model, Pachepskey [23] divided the population into two interacting compartments: individuals residing on the benthos (the bottom of the stream) and individuals drifting in the flow. They considered a population in which individuals live and reproduce on the benthos, and occasionally enter the water column to drift until they settle on the benthos again.

The importance of compartmentalization is that aquatic insect larvae spend a considerable proportion of their time immobile on the benthos [21]. For example, zebra mussels have two life stages: a free floating larval stage and an attached adult stage. Larvae are planktonic for 2-4 weeks and adults are sessile. They spend 2% of their lifetime in the water column. Moreover, the rates that insects switch between benthos and drift can be set by insect behavior rather than by stream hydrodynamics. For instance, some experiments showed that the entry rate to the

drift can depend on the organisms response to environmental factors such as food abundance and density dependence [1, 21, 22], and the settling rate to the benthos can be approximately constant for some species [17].

Pachepskey's model was given by

$$\begin{aligned}\frac{\partial n_d}{\partial t} &= D \frac{\partial^2 n_d}{\partial x^2} - v \frac{\partial n_d}{\partial x} + \mu n_b - \sigma n_d \\ \frac{\partial n_b}{\partial t} &= f(n_b) n_b - \mu n_b + \sigma n_d,\end{aligned}\tag{1.2}$$

where n_d is the population density in the drift; n_b is the population density on the benthos; μ is the per capita rate at which individuals in the benthic population enter the drift; σ is the per capita rate at which the insects return to the benthos from the stream. In their work, they gave the critical domain size necessary for population persistence, showed the positive effect of the stationary component on the ability of the population to persist and spread by analyzing the propagation speed of a population with two compartments. Some numerical results include:

1. The persistence of the population is guaranteed if, at low population densities, the local growth rate of the stationary component of the population exceeds the rate of entry of individuals into the drift;
2. Persistence and ability to spread are closely connected: if the population cannot advance upstream against the flow, it also cannot persist on any finite spatial domain;
3. Residence in the immobile state always enhances population persistence.

However, Pachepskey did not consider stage structure and time-delay for the individuals to reach maturity from when they were born. A large number of papers have been written on modeling single-species population growth with various life stages using discrete models [25, 26, 27], continuous models [28, 29, 30, 31, 32, 33, 34], and stochastic models [35]. Aiello [24] developed a single-species

growth model with stage structure consisting of immature and mature stages using a discrete time delay from birth to maturity. They showed that there exists a globally asymptotically stable positive equilibrium under certain conditions and analytically and numerically addressed oscillation properties of solutions with time-delay being considered. But they do not consider multiple species with competition and existence of traveling wave solutions.

In this dissertation I construct a stage-structured delayed reaction-diffusion model with competition between two species in a stream. This model has the benefit of synthesizing and generalizing many of the aforementioned models, while providing a clear focus on persistence of two species in a water flow.

In the construction of our system we allow different time delays for both species from birth to maturity and compartmentalization. We include a classical Lotka-Volterra type term which describes the interspecific competition between the two different species. We also involve two stages of life history, immature and mature, for both species.

In this chapter we aim to give the reader a brief but sufficient introduction on reaction-diffusion equations and delay differential equations so that the core content and results of this dissertation are accessible. Section 1.2 introduces the concept of a reaction-diffusion equation and main results of spreading speeds and traveling wave solutions. Section 1.3 introduces delay differential equations and the typical methodology employed to analyze and study them.

1.2 Reaction-Diffusion Equations

Reaction-diffusion equations model the movement of many individuals in an environment or media and a local reaction kinetics such as birth, death, and other reaction process. Reaction-diffusion systems can explain the effects of

the size, shape, and heterogeneity of the spatial environment on the persistence of species and the structure of communities in ecology. Reaction ($R(u)$) and diffusion (diffusion coefficient D) both contribute to the interesting dynamical behavior of the solutions of the equation. We may describe the above mechanism by the classical FKPP (Fisher's equation) reaction-diffusion equation [36, 37]

$$\frac{\partial u}{\partial t} = D \frac{\partial^2 u}{\partial x^2} + R(u), \quad (1.3)$$

where $R(u) = u(1 - u)$.

Diffusion can be considered as a random walk which starts at a point and takes steps in a random direction. Fick's laws can be used to solve for the diffusion coefficient, D , and it addresses that the diffusive flux goes from regions of high concentration to regions of low concentration. A special solution of the equation (1.3) is a propagating front (also called traveling wave solution), separating two non-equilibrium homogeneous states, one of which ($u = 1$) is stable and another one ($u = 0$) is unstable [38, 39, 40]. Figure 1.1 depicts a numerical solution of the FKPP equation (1.3) for six different time moments $t = 0, 100, 200, 400, 600, 800$ with initial condition $u(x, 0) = f(x) = .05e^{-5x^2}$.

We notice, from Figure 1.1, that a small local initial fluctuation around $u = 0$ leads to an instability, and that develops in a nonlinear way: a front propagates away from the initial perturbation. Finally, the uniformly stable state of $u = 1$ is established on the whole space interval.

In the real world, there are many cases that species live in the media where the diffusion moves to a certain direction. For example, the seeds flow in the wind and organisms drift in the water flow. When one direction in the random walk is favored, an equation with a first order derivative is the result:

$$\frac{\partial u}{\partial t} = D \frac{\partial^2 u}{\partial x^2} - v \frac{\partial u}{\partial x} + R(u). \quad (1.4)$$

FIGURE 1.1–Traveling wave solutions of FKPP equation, $\frac{\partial u}{\partial t} = D \frac{\partial^2 u}{\partial x^2} + R(u)$, where $R = u - u^2$

The first order derivative term on the right hand side of the equation (1.4) is called an advection term, and the equation (1.4) is called a **reaction-diffusion equation with advection**.

1.3 Delay Differential Equations

Delay differential equations (DDEs) are a type of differential equation in which the derivative of the unknown function at a certain time is given in terms of the values of the function at previous times. We use DDEs because many of the processes in the fields including biology, medicine, chemistry, physics, engineering, and economics involve time delays. For example, in physical processes acceleration and deceleration take little time compared to the times needed to travel most distances, and in biological processes maturation time durations can be large compared to the data-collection times in most population studies. One simple example of DDEs is the Hutchinson equation:

FIGURE 1.2–Solutions of the Hutchinson equation, $\frac{dx(t)}{dt} = rx(1 - x(t - \tau)/K)$, where $\tau = 1, 3$

$$\frac{dx(t)}{dt} = rx(1 - x(t - \tau)/K). \quad (1.5)$$

The dynamics of DDEs is more complex than that of ordinary differential equations (ODEs). Figure 1.2 shows solutions of the Hutchinson equation with delays $\tau = 1$ and 3 , respectively, and gives complex dynamics such as excessive volatility and huge peak-to-valley ratios [43].

DDEs are mostly solved using the “method of steps” given initial condition $\phi : [-\tau, 0] \rightarrow \mathbb{R}^n$. Then the solution on the interval $[0, \tau]$ is obtained and is the solution to the inhomogeneous initial value problem

$$\begin{aligned}\frac{du(t)}{dt} &= -u(t - \tau), \quad \tau > 0 \\ u(t) &= \phi(t), \quad t \in [-\tau, 0].\end{aligned}\tag{1.6}$$

This can be continued for the successive intervals by using the solution to the previous interval as an inhomogeneous term. In practice, the initial value problem is often solved numerically. Moreover, the existence of solutions of the initial value problem has been given in Theorem 1.1.

THEOREM 1.1. *Let $f, f_x \in \mathcal{C}(\mathbb{R}^3)$, $s \in \mathbb{R}$ and let $\phi : [s - \tau, s] \rightarrow \mathbb{R}$ be a continuous function. Then there exists $\sigma > s$ and a unique solution of the initial value problem*

$$\begin{aligned}\frac{du(t)}{dt} &= f(t, x(t), x(t - \tau)), \quad \tau > 0 \\ u(t) &= \phi(t), \quad t \in [s - \tau, s].\end{aligned}$$

on $[s - \tau, \sigma]$.

Existence of solutions of delayed reaction-diffusion systems was established by Martin and Smith [45].

Similar to ODEs, many properties including stability of linear DDEs can be characterized and analyzed using the characteristic equation. The characteristic equation associated with the linear DDE with discrete delays

$$\frac{dx(t)}{dt} = A_0x(t) + A_1x(t - \tau_1) + \dots + A_nx(t - \tau_n)$$

is

$$\det(-\lambda I + A_0 + A_1e^{-\tau_1\lambda} + \dots + A_ne^{-\tau_n\lambda}) = 0.$$

Because of the exponential in the characteristic equation, the DDE has infinitely many eigenvalues and thus is more complicated to analyze its properties. There are some studies being done to determine the stability of DDEs [41, 42, 43]. Aiello and Freedman [46] developed a time-delay model of single-species growth with stage structure and showed that under suitable hypotheses there exists a

globally asymptotically stable positive equilibrium. Zhang et al. [64] studied the stability and travelling waves for a time-delayed population system with stage structure. However, it is known that some delay systems experience a change in stability as the time delay increases, while such systems do not experience such changes, the stability problem has not been solved for many general DDEs.

The Spreading Speed

In mathematics, many studies have been done to explain why species persist and even spread against the downstream flow and how quickly a population is advancing or retreating in its environment. As a mechanism to quantify spread we consider the asymptotic behavior of the solution as x approaches infinity, and this is called the **spreading speed** introduced by Aronson and Weinberger [47, 48, 49] for reaction-diffusion equations. We focus on the spreading speed and traveling wave solutions as resolutions of the drift paradox.

For the classical reaction-diffusion equation (1.3) we define the spreading speed c^* in the following sense:

1. If $0 \leq u(x, 0) < 1$ and $u(x, 0) \equiv 0$ for all sufficiently large x , then for any positive ϵ

$$\lim_{x \rightarrow \infty} \left\{ \max_{|x| \geq (c^* + \epsilon)t} u(x, t) \right\} = 0. \quad (1.7)$$

2. For every positive number σ there exists a positive number r_σ such that if $0 \leq u(x, 0) \leq 1$, and if $u(x, 0) \geq \sigma$ on an interval of length r_σ , then for any positive ϵ ,

$$\lim_{x \rightarrow \infty} \left\{ \sup_{|x| \leq (c^* - \epsilon)t} (1 - u(x, t)) \right\} = 0. \quad (1.8)$$

The first statement says that c^* is an upper bound for the spreading speed. If c^* is the asymptotic rate of spread, then we would expect that at time t , the support of the solution would have grown by c^*t . Thus, points outside the expected support of the solution ($|x| \geq (c^* + \epsilon)t$) should not have individuals present. In other words, if we always move faster than the rate of spread of the population, we should always be in front of the advancing population.

Alternatively, the second statement says that c^* is a lower bound for the spreading speed. If we always move more slowly than the population ($|x| \leq (c^* - \epsilon)t$) then we should always be behind the leading edge of the advancing population.

FIGURE 1.3–Spread of the solution of FKPP equation with the speed of $c^* = 2\sqrt{DR'(0)}$

In this case, the population will approach the steady-state, 1, over a long period of time.

Connecting the first and second statements we conclude that c^* is the asymptotic rate of spread of the solutions of the reaction-diffusion equation (1.3).

Aronson and Weinberger [48, 49] proved that the spreading speed of FKPP equation (1.3) is given by $c^* = 2\sqrt{DR'(0)}$ and the compact initial data expands at speed c^* .

The formula $c^* = 2\sqrt{DR'(0)}$ can be obtained a similar formula through an abstract operator Q , the time one solution map of (1.3),

$$u(x, t) = Q[u_0](x), \quad u_0 = u(0, x) \quad (1.9)$$

and its linearization map M defined by

$$M[u](x) = \int_{-\infty}^{\infty} u(x-y)m(y)dy, \quad (1.10)$$

where u is a vector of population distributions of species, Q is the time one solution map which models the growth, interaction, and migration of the species, and $m(y) = R'(0)\frac{1}{2\sqrt{\pi D}}e^{-\frac{|y|^2}{4D}}$ is a nonnegative bounded measure [51]. In [51] Weinberger also provided the formula of the spreading speed c^* for the reaction-diffusion equation with advection (1.4), $c^* = v + 2\sqrt{DR'(0)}$.

For a nonlinear multi-species reaction-diffusion system, there are multiple spreading speeds. The slowest spreading speed c^* and the fastest spreading speed c_+^* are given by Weinberger et al. [52] and Li et al. [61]. An upper bound of all spreading speeds c_+^* is also given in [52]. Moreover, if the nonlinear system is dominated by a linear system in the direction of the vector corresponding to the principal eigenvalue of the generating matrix, then the nonlinear system has a unique spreading speed (i.e. $c^* = c_+^*$), which is equal to that of the linear system [52]. This is known as **linear determinacy**. Li [53] studied partially degenerate cooperative reaction-diffusion systems, and the result can be applied on Pachepskey's model (1.2).

In the next section we will discuss how the spreading speed is related to traveling wave speeds.

FIGURE 1.4 – Traveling wave solution of the reaction-diffusion equation $u(x, t) = w(x - ct)$ with $w(-\infty) = 1$ and $w(+\infty) = 0$ exists if and only if $c \geq c^*$.

Traveling Wave Solutions

We consider the continuous-time problems such as the reaction-diffusion system

$$\begin{aligned} \mathbf{u}_t &= D\mathbf{u}_{,xx} - E\mathbf{u}_{,x} + \mathbf{f}(\mathbf{u}), \\ \mathbf{u}(0, x) &= \mathbf{u}_0(x) \end{aligned} \tag{1.11}$$

where $D := \text{diag}(d_1, d_2, \dots, d_k)$ and $E := \text{diag}(e_1, e_2, \dots, e_k)$ are constant diagonal matrices. A traveling wave of the reaction-diffusion system (1.11) with speed c is a solution in the form of $\mathbf{W}(x - ct)$, where c is a positive constant.

Note that traveling wave solutions do not explicitly depend on time. Indeed, they are solutions retaining their shapes which are translated by a fixed length for each iteration of time. Thus the solutions travel in space at the rate of c over time.

There have been a number of investigations of traveling wave solutions and asymptotic behavior in terms of spreading speeds for various evolution systems including nonlinear reaction-diffusion systems [54, 55, 56] and time-delayed reaction-diffusion systems [57, 58, 59, 62]. Weinberger, Lewis and Li [52, 60, 61] developed the theory of spreading speeds and monotone traveling wave solutions for cooperative or competition models. For the reaction-diffusion equations (1.11) without the advection term, it has been proved that the spreading speed c^* can be characterized as the slowest speed of a class of traveling wave solutions when all the diffusion coefficients $d_i > 0$ [61]. Furthermore, the above statement holds if all the linear determinacy conditions are satisfied when some but not all $d_i = 0$ [53].

Under appropriate assumptions, when $c \geq c^*$ there exists a traveling wave solution $w(x - ct)$ which is non-increasing, and when $c < c^*$ there is no traveling wave solution with speed c .

For a delayed Lotka-Volterra type competition model, Al-Omari and Gourley [63] showed that for $c \geq \tilde{c}$, where \tilde{c} is some number, the system has a nondecreasing traveling wave solution connecting two mono-culture equilibria. Liang and Zhao [67] discussed the existence of spreading speed and traveling wave solutions for general delayed systems. Recently, Li and Zhang [62] proved the existence of traveling wave solutions that connect a mono-culture equilibrium and a different mono-culture equilibrium.

The connection between spreading speeds and traveling wave speeds is significant because it is often more accessible to calculate the minimum speed of traveling waves than it is to calculate the spreading speed.

CHAPTER 2

THE MODEL

In this chapter we introduce a stage-structured delayed reaction-diffusion model for competition between two species in a stream. The construction of our model can be divided into two steps:

1. **The Delayed Reaction-Diffusion Equations For Single Species With Stage Structure:** Construction of the delayed reaction-diffusion equations is used to describe the growth processes of a single species with advection, diffusion, and stage structure in a stream.
2. **The Lotka-Volterra-type Competition Model Between Two Species:** We introduce another species with similar growth processes while considering the Lotka-Volterra-type competition between the adult members to describe the interaction between two species in a stream subjected to advection and diffusion.

2.1 Delayed Reaction-Diffusion Equations For Single Species With Stage Structure

We begin with an extension of Pachepskey's model (1.2) as a delayed reaction-diffusion two-patch model with age structure. In our single species model, there are two interacting compartments: individuals residing on the benthos and individuals drifting in the flow, as was stated in Pachepskey's model. Individuals live and reproduce on the benthos, and occasionally enter the water column to drift

until they settle on the benthos again. We assume that only adult members on the benthos could switch themselves between two compartments and the immature individuals always stay on the stationary compartment until they grow to maturity during a period of time. Therefore, we describe our assumption by introducing the stage structure among the population on the benthos and using n_{bi} and n_{bm} to represent the population density of immature members and the population density of mature members on the benthos, respectively. Moreover, we incorporate a time delay which represents the time from birth to maturity of the benthic population.

Before giving our model for single species, we make the following assumptions:

1. Assume that the rate of drift entry is constant, but the model we present is formulated in a way that allows us to easily modify and improve these factors in future work.
2. Assume that (a) transfer between mobile and stationary compartments is via a Poisson process, (b) individual movement can be described as a combination of advection corresponding to the one-dimensional medium with a unidirectional flow as experienced by the organisms and diffusion corresponding to the heterogeneous stream flow and individual swimming, and (c) reproduction occurs on a local scale, i.e. adult members lay eggs where they emerge. These assumptions are intuitively reasonable and have been used in plant population models as well [23, 64].

Our delayed reaction-diffusion two-compartment model with age structure for one species is given by:

$$\begin{aligned}
\frac{\partial n_d}{\partial t} &= d \frac{\partial^2 n_d}{\partial x^2} - e \frac{\partial n_d}{\partial x} + \delta n_{bm} - \sigma n_d \\
\frac{\partial n_{bi}}{\partial t} &= r n_{bm} - \beta n_{bi} - r e^{-\beta \tau} n_{bm}(t - \tau, x) \\
\frac{\partial n_{bm}}{\partial t} &= r e^{-\beta \tau} n_{bm}(t - \tau, x) - \frac{r(n_{bm})^2}{\kappa} - \delta n_{bm} + \sigma n_d.
\end{aligned} \tag{2.1}$$

Here, the last term on the right hand side of the second equation represents the individuals on the benthos born at time $t - \tau$ that are still alive at time t and have reached maturity and arrived at x . The death rate of the mature on the benthos is modelled by quadratic term, as in the logistic equation.

Table 2.1 gives a description of each parameter mentioned above.

2.2 Two Species Lotka-Volterra-type Competition Model

We next introduce another species with similar growth processes. In order to study how two competing species can persist in streams for some common and limited resource, we use the Lotka-Volterra formulation and add an additional term for each species to account for the species' interactions. We assume that the competition only occurs between the benthic adult individuals and all interactions must be harmful. Our Lotka-Volterra-type competition model is given by:

$$\begin{aligned}
\frac{\partial n_d^{(1)}}{\partial t} &= d_1 \frac{\partial^2 n_d^{(1)}}{\partial x^2} - e_1 \frac{\partial n_d^{(1)}}{\partial x} + \delta_1 n_{bm}^{(1)} - \sigma_1 n_d^{(1)} \\
\frac{\partial n_{bi}^{(1)}}{\partial t} &= r_1 n_{bm}^{(1)} - \beta_1 n_{bi}^{(1)} - r_1 e^{-\beta_1 \tau_1} n_{bm}^{(1)}(t - \tau_1, x) \\
\frac{\partial n_{bm}^{(1)}}{\partial t} &= r_1 e^{-\beta_1 \tau_1} n_{bm}^{(1)}(t - \tau_1, x) - \frac{r_1 (n_{bm}^{(1)})^2}{\kappa_1} - \delta_1 n_{bm}^{(1)} + \sigma_1 n_d^{(1)} - c_1 n_{bm}^{(1)} n_{bm}^{(2)} \\
\frac{\partial n_d^{(2)}}{\partial t} &= d_2 \frac{\partial^2 n_d^{(2)}}{\partial x^2} - e_2 \frac{\partial n_d^{(2)}}{\partial x} + \delta_2 n_{bm}^{(2)} - \sigma_2 n_d^{(2)} \\
\frac{\partial n_{bi}^{(2)}}{\partial t} &= r_2 n_{bm}^{(2)} - \beta_2 n_{bi}^{(2)} - r_2 e^{-\beta_2 \tau_2} n_{bm}^{(2)}(t - \tau_2, x) \\
\frac{\partial n_{bm}^{(2)}}{\partial t} &= r_2 e^{-\beta_2 \tau_2} n_{bm}^{(2)}(t - \tau_2, x) - \frac{r_2 (n_{bm}^{(2)})^2}{\kappa_2} - \delta_2 n_{bm}^{(2)} + \sigma_2 n_d^{(2)} - c_2 n_{bm}^{(1)} n_{bm}^{(2)},
\end{aligned} \tag{2.2}$$

where all the parameters have the same descriptions as those in Table 2.1 with the indices $i = 1, 2$ indicating the first and second species, respectively, that we consider. As we mentioned at the beginning of this section, we include an addi-

TABLE 2.1

One Species Model - Parameter Descriptions

Parameter	Description of Parameter
$n_d(x, t)$	population density in the drift at time t and point x
$n_{bi}(x, t)$	population density of immature members on the benthos at time t and point x
$n_{bm}(x, t)$	population density of mature members on the benthos at time t and point x
d	diffusion coefficient
e	advection speed experienced by the organisms
δ	rate at which adult individuals on the benthos enter the drift
σ	rate at which adult individuals return to the benthos from drifting
r	birth rate of the population
β	death rate of the population
τ	time delay from birth to maturity
κ	maximum population density that the environment can carry (carrying capacity)

TABLE 2.2

Simplified Competition Model - Simplified Parameter Descriptions

Parameter	Description of Parameter
$n_b^{(i)}$	population density of adult members of the i th species on the benthos at time t and point x , $i = 1, 2$
r_i	rate combining two factors: the per capita birth rate and the survival rate of the immature for the i th species during the immature stage, $i = 1, 2$

tional term for each species to account for their competitions. The parameter c_1 represents the effect the second species has on the mature of the first species and c_2 represents the effect the first species has on the mature of the second species. Also, the definition of a competitive Lotka-Volterra system assumes that all c -values are positive.

Note that the third and sixth equations in system (2.2) are uncoupled from the second and fifth equations, it is sufficient to consider a simplified system with the second and fifth equations merged:

$$\begin{aligned}
 \frac{\partial n_d^{(1)}}{\partial t} &= d_1 \frac{\partial^2 n_d^{(1)}}{\partial x^2} - e_1 \frac{\partial n_d^{(1)}}{\partial x} + \delta_1 n_b^{(1)} - \sigma_1 n_d^{(1)} \\
 \frac{\partial n_b^{(1)}}{\partial t} &= r_1 n_b^{(1)}(t - \tau_1, x) - \frac{r_1 (n_b^{(1)})^2}{\kappa_1} - \delta_1 n_b^{(1)} + \sigma_1 n_d^{(1)} - c_1 n_b^{(1)} n_b^{(2)} \\
 \frac{\partial n_d^{(2)}}{\partial t} &= d_2 \frac{\partial^2 n_d^{(2)}}{\partial x^2} - e_2 \frac{\partial n_d^{(2)}}{\partial x} + \delta_2 n_b^{(2)} - \sigma_2 n_d^{(2)} \\
 \frac{\partial n_b^{(2)}}{\partial t} &= r_2 n_b^{(2)}(t - \tau_2, x) - \frac{r_2 (n_b^{(2)})^2}{\kappa_2} - \delta_2 n_b^{(2)} + \sigma_2 n_d^{(2)} - c_2 n_b^{(1)} n_b^{(2)}.
 \end{aligned} \tag{2.3}$$

Some new parameters appear in our simplified model (2.3). A description of these parameters can be found in Table 2.2.

In next chapters, we study the system (2.3) analytically and numerically. Before that, we summarize the importance of our extension and difficulties of the

model study as follows:

Importance of Our Extension

1. Many biological species reproduce themselves, but it takes some time for the subsequent generation to mature and reproduce.
2. Competition both within and between species is an important topic in ecology, especially community ecology. Competition is one of many interacting biotic and abiotic factors that affect community structure.

Difficulties of The Model Study

1. The system with delay differential equations is hard to analyze its global stability using general methods.
2. Since each species has two compartments, we have four equations including two DDEs, which increases the difficulty of the proof of existence of traveling wave solutions and the formulation of the spreading speed.

CHAPTER 3

NONSPATIAL SYSTEM ANALYSIS

In this chapter we consider only the nonspatial system which models the growth and dispersal of two stage-structured interactive species without the effect of spatial advection and diffusion. We demonstrate that the global stability of the equilibria in the model can be completely determined. The mathematical analysis involves using the fluctuation lemma and constructing sequences approaching equilibrium points.

3.1 Nonspatial System

Based on the model (2.3), the corresponding nonspatial system is yield:

$$\begin{aligned}
\frac{\partial n_d^{(1)}}{\partial t} &= \delta_1 n_b^{(1)} - \sigma_1 n_d^{(1)} \\
\frac{\partial n_b^{(1)}}{\partial t} &= r_1 n_b^{(1)}(t - \tau_1, x) - \frac{r_1 (n_b^{(1)})^2}{\kappa_1} - \delta_1 n_b^{(1)} + \sigma_1 n_d^{(1)} - c_1 n_b^{(1)} n_b^{(2)} \\
\frac{\partial n_d^{(2)}}{\partial t} &= \delta_2 n_b^{(2)} - \sigma_2 n_d^{(2)} \\
\frac{\partial n_b^{(2)}}{\partial t} &= r_2 n_b^{(2)}(t - \tau_2, x) - \frac{r_2 (n_b^{(2)})^2}{\kappa_2} - \delta_2 n_b^{(2)} + \sigma_2 n_d^{(2)} - c_2 n_b^{(1)} n_b^{(2)}
\end{aligned} \tag{3.1}$$

with initial conditions

$$n_d^{(i)}(t), n_b^{(i)}(t) \geq 0 \text{ for } -\tau_i \leq t \leq 0, \text{ and } n_d^{(i)}(0), n_b^{(i)}(0) > 0 \text{ for } i = 1, 2. \tag{3.2}$$

It is easy to show that the system (3.1) has the trivial equilibrium $E_0 = (0, 0, 0, 0)$, the mono-culture equilibria $E_1 = (\frac{\delta_1 \kappa_1}{\sigma_1}, \kappa_1, 0, 0)$ and $E_2 = (0, 0, \frac{\delta_2 \kappa_2}{\sigma_2}, \kappa_2)$, and the coexistence equilibrium

$$E^* = \left(\frac{\delta_1 \kappa_1 r_2 (c_1 \kappa_2 - r_1)}{(c_1 c_2 \kappa_1 \kappa_2 - r_1 r_2) \sigma_1}, \frac{\kappa_1 r_2 (c_1 \kappa_2 - r_1)}{c_1 c_2 \kappa_1 \kappa_2 - r_1 r_2}, \frac{\delta_2 \kappa_2 r_1 (c_2 \kappa_1 - r_2)}{(c_1 c_2 \kappa_1 \kappa_2 - r_1 r_2) \sigma_2}, \frac{\kappa_2 r_1 (c_2 \kappa_1 - r_2)}{c_1 c_2 \kappa_1 \kappa_2 - r_1 r_2} \right).$$

TABLE 3.1

Summary of Existence and Local Stability Criteria of Equilibria

Equilibrium	Existence Criteria	Stability Criteria
E_0	always exists	always unstable
E_1	always exists	$r_2 < c_2\kappa_1$
E_2	always exists	$r_1 < c_1\kappa_2$
E^*	If $c_1c_2\kappa_1\kappa_2 > r_1r_2$, $r_1 < c_1\kappa_2$ and $r_2 < c_2\kappa_1$ If $c_1c_2\kappa_1\kappa_2 < r_1r_2$, $r_1 > c_1\kappa_2$ and $r_2 > c_2\kappa_1$	The global stability analysis in section 3.3 shows that E^* is asymptotically stable if $r_1 > c_1\kappa_2$ and $r_2 > c_2\kappa_1$.

3.2 Local Stability

We study local stabilities of the equilibria by analyzing the characteristic equations of the linearized system. Here we sketch an outline of our analysis of local stability criteria. Table 3.1 is the summary of our analytical results.

Outline for Local Stability Criteria:

1. Find the characteristic equations of the linearized system for each equilibrium point;
2. Analyze the local stability when there is no time delay in the system, i.e. when $\tau_i = 0$, $i = 1, 2$;
3. Apply the theorem in [43] to the above analysis and get local stability criteria.

3.3 Global Stability

In this section, we shall prove Theorem 3.1 on the global asymptotic stability of the equilibria E_1 , E_2 , and E^* . Since positivity implies that the system is

persistent, by the initial condition (3.2), the persistence of the nonspatial system (3.1) is guaranteed.

Before proceeding, we need the following lemmas.

The following two lemmas are elementary but useful in our proof. These were proven in [65, 66].

LEMMA 3.1. (*Barbălat Lemma*) *Let a be a finite number, and $f : [a, \infty) \rightarrow \mathbb{R}$ be a differentiable function. If $\lim_{t \rightarrow \infty} f(t)$ exists (finite) and f' is uniformly continuous on $[a, \infty)$, then $\lim_{t \rightarrow \infty} f'(t) = 0$.*

LEMMA 3.2. (*Fluctuation Lemma*) *Let a be a finite number, and $f : [a, \infty) \rightarrow \mathbb{R}$ be a differentiable function. If $\liminf_{t \rightarrow \infty} f(t) < \limsup_{t \rightarrow \infty} f(t)$, then there exist sequences $\{t_m\} \uparrow \infty$ and $\{s_m\} \uparrow \infty$ such that $\lim_{m \rightarrow \infty} f(t_m) = \limsup_{t \rightarrow \infty} f(t)$, $f'(t_m) = 0$, and $\lim_{m \rightarrow \infty} f(s_m) = \liminf_{t \rightarrow \infty} f(t)$, $f'(s_m) = 0$.*

Lemma 3.2 states that for an oscillating function f , we can always find two sequences satisfying the above conditions. Using Lemma 3.2, we can study the long-term behavior by knowing what happens at the local minimum and maximum points.

LEMMA 3.3. *Consider the following one-species system*

$$\begin{aligned} \frac{\partial n_d^{(1)}}{\partial t} &= \delta_1 n_b^{(1)} - \sigma_1 n_d^{(1)} \\ \frac{\partial n_b^{(1)}}{\partial t} &= r_1 n_b^{(1)}(t - \tau_1, x) - \frac{r_1 (n_b^{(1)})^2}{\kappa_1} - \delta_1 n_b^{(1)} + \sigma_1 n_d^{(1)}. \end{aligned} \tag{3.3}$$

Let $(n_d^{(1)}(t), n_b^{(1)}(t))$ be the solution of system (3.3), where $n_d^{(1)}(t), n_b^{(1)}(t) > 0$ for $-\tau_1 \leq t \leq 0$. Then $\lim_{t \rightarrow \infty} (n_d^{(1)}(t), n_b^{(1)}(t)) = (\frac{\delta_1 \kappa_1}{\sigma_1}, \kappa_1)$.

Proof. We shall prove the lemma with three cases:

Case i: When $(n_d^{(1)}(t), n_b^{(1)}(t))$ is eventually monotonically decreasing, positivity of solutions indicates that $(n_d^{(1)}(t), n_b^{(1)}(t))$ must approach some limit $\hat{N}_1 \geq \mathbf{0}$. This limit must be an equilibrium of (3.3) and is therefore either $\mathbf{0}$ or $(\frac{\delta_1 \kappa_1}{\sigma_1}, \kappa_1)$.

The trivial equilibrium $\mathbf{0}$ is ruled out since it is unstable by the local stability analysis in Section 3.2.

Case ii: When $(n_d^{(1)}(t), n_b^{(1)}(t))$ is eventually monotonically increasing, then $n_b^{(1)}(t - \tau_1, x) \leq n_b^{(1)}(t)$ for some sufficiently large t and all $\tau_1 \in [0, \tau]$ so that

$$\frac{\partial n_b^{(1)}}{\partial t} \leq r_1 n_b^{(1)}(t, x) - \frac{r_1 (n_b^{(1)})^2}{\kappa_1} - \delta_1 n_b^{(1)} + \sigma_1 n_d^{(1)}.$$

Hence $\lim_{t \rightarrow \infty} (n_d^{(1)}(t), n_b^{(1)}(t))$ exists and is an positive equilibrium of (3.3), i.e.

$$\lim_{t \rightarrow \infty} (n_d^{(1)}(t), n_b^{(1)}(t)) = \left(\frac{\delta_1 \kappa_1}{\sigma_1}, \kappa_1 \right).$$

Case iii: $(n_d^{(1)}(t), n_b^{(1)}(t))$ is neither eventually monotonically decreasing nor increasing. It means that $n_d^{(1)}(t)$ and $n_b^{(1)}(t)$ have infinite sequences of local maxima and local minima. Define

$$\begin{aligned} \limsup_{t \rightarrow \infty} n_d^{(1)}(t) &= \overline{n_d^{(1)}}, \\ \liminf_{t \rightarrow \infty} n_d^{(1)}(t) &= \underline{n_d^{(1)}}, \\ \limsup_{t \rightarrow \infty} n_b^{(1)}(t) &= \overline{n_b^{(1)}}, \text{ and} \\ \liminf_{t \rightarrow \infty} n_b^{(1)}(t) &= \underline{n_b^{(1)}}. \end{aligned}$$

By Lemma 3.2, there exist $\{t_{1n}^{(+)}\}$, $\{t_{1n}^{(-)}\}$, $\{s_{1n}^{(+)}\}$, and $\{s_{1n}^{(-)}\}$ such that

$$\begin{aligned} n_d^{(1)}(t_{1n}^{(+)}) &\rightarrow \overline{n_d^{(1)}} \text{ as } t \rightarrow \infty, & n_d^{(1)}(t_{1n}^{(-)}) &\rightarrow \underline{n_d^{(1)}} \text{ as } t \rightarrow \infty, \\ n_b^{(1)}(s_{1n}^{(+)}) &\rightarrow \overline{n_b^{(1)}} \text{ as } t \rightarrow \infty, & n_b^{(1)}(s_{1n}^{(-)}) &\rightarrow \underline{n_b^{(1)}} \text{ as } t \rightarrow \infty \end{aligned}$$

where $(n_d^{(1)}(t_{1n}^{(\pm)}))' = 0$ and $(n_b^{(1)}(s_{1n}^{(\pm)}))' = 0$.

Since $\delta_1 \underline{n_b^{(1)}} \leq \sigma_1 \underline{n_d^{(1)}} \leq \sigma_1 \overline{n_d^{(1)}} \leq \delta_1 \overline{n_b^{(1)}}$, we have $\sigma_1 \Delta n_d^{(1)} \leq \delta_1 \Delta n_b^{(1)}$, where $\Delta n_d^{(1)} = \overline{n_d^{(1)}} - \underline{n_d^{(1)}}$ and $\Delta n_b^{(1)} = \overline{n_b^{(1)}} - \underline{n_b^{(1)}}$.

Now considering the second equation of system (3.3), we have

$$0 = r_1 n_b^{(1)}(s_{1n}^{(\pm)} - \tau_1) - \frac{r_1 (n_b^{(1)}(s_{1n}^{(\pm)}))^2}{\kappa_1} - \delta_1 n_b^{(1)}(s_{1n}^{(\pm)}) + \sigma_1 n_d^{(1)}(s_{1n}^{(\pm)}).$$

Taking the limit of both sides of the above equation as $t \rightarrow \infty$, then

$$0 = r_1 \widehat{n_b^{(1+)}} - \frac{r_1 (\overline{n_b^{(1)}})^2}{\kappa_1} - \delta_1 \overline{n_b^{(1)}} + \sigma_1 \widehat{n_d^{(1+)}}$$

and

$$0 = r_1 \widehat{n_b^{(1-)}} - \frac{r_1 (n_b^{(1)})^2}{\kappa_1} - \delta_1 \underline{n_b^{(1)}} + \sigma_1 \widehat{n_d^{(1-)}},$$

where $\widehat{n_b^{(1\pm)}} := \lim_{t \rightarrow \infty} n_b^{(1)}(s_{1n}^{(\pm)} - \tau_1)$ and $\widehat{n_d^{(1\pm)}} := \lim_{t \rightarrow \infty} n_d^{(1)}(s_{1n}^{(\pm)})$.

Since $\underline{n_b^{(1)}} \leq \widehat{n_b^{(1\pm)}} \leq \overline{n_b^{(1)}}$, and $\underline{n_d^{(1)}} \leq \widehat{n_d^{(1\pm)}} \leq \overline{n_d^{(1)}}$, then

$$\begin{aligned} \overline{n_b^{(1)}} + \sigma_1 \overline{n_d^{(1)}} - \frac{r_1 (\overline{n_b^{(1)}})^2}{\kappa_1} - \delta_1 \overline{n_b^{(1)}} &\geq 0 \\ r_1 \underline{n_b^{(1)}} + \sigma_1 \underline{n_d^{(1)}} - \frac{r_1 (\underline{n_b^{(1)}})^2}{\kappa_1} - \delta_1 \underline{n_b^{(1)}} &\leq 0. \end{aligned}$$

Since $\overline{\sigma_1 n_d^{(1)}} \leq \delta_1 \overline{n_b^{(1)}}$ and $\sigma_1 \underline{n_d^{(1)}} \geq \delta_1 \underline{n_b^{(1)}}$, then

$$\begin{aligned} \overline{n_b^{(1)}} \left[r_1 - \frac{r_1 \overline{n_b^{(1)}}}{\kappa_1} \right] &\geq 0 \\ \underline{n_b^{(1)}} \left[r_1 - \frac{r_1 \underline{n_b^{(1)}}}{\kappa_1} \right] &\leq 0. \end{aligned}$$

If $\overline{n_b^{(1)}} \neq 0$, $\overline{n_b^{(1)}} \leq \kappa_1$, and if $\underline{n_b^{(1)}} \neq 0$, $\underline{n_b^{(1)}} \geq \kappa_1$, then $\overline{n_b^{(1)}} \leq \underline{n_b^{(1)}}$. Thus $\overline{n_b^{(1)}} = \underline{n_b^{(1)}}$ and $\Delta n_b^{(1)} = 0$. Since $0 \leq \sigma_1 \Delta n_d^{(1)} \leq \delta_1 \Delta n_b^{(1)}$, we have $\Delta n_d^{(1)} = 0$.

We know that $\frac{\partial n_d^{(1)}}{\partial t}$ and $\frac{\partial n_b^{(1)}}{\partial t}$ are bounded, and that $(0, 0)$ is locally unstable.

By Persistence Theory, $\underline{n_d^{(1)}}, \underline{n_b^{(1)}} > 0$ and $\lim_{t \rightarrow \infty} (n_d^{(1)}(t), n_b^{(1)}(t)) = (\frac{\delta_1 \kappa_1}{\sigma_1}, \kappa_1)$. The proof of Lemma (3.3) is complete.

Using a similar argument, we can show that $\lim_{t \rightarrow \infty} (n_d^{(2)}(t), n_b^{(2)}(t)) = (\frac{\delta_2 \kappa_2}{\sigma_2}, \kappa_2)$.

□

THEOREM 3.1. *Let E_1, E_2 and E^* be defined as above, then the following statements are valid:*

- i. If $r_1 > c_1 \kappa_2, r_2 < c_2 \kappa_1$, then the mono-culture equilibrium E_1 is globally asymptotically stable;*
- ii. If $r_1 < c_1 \kappa_2, r_2 > c_2 \kappa_1$, then the mono-culture equilibrium E_2 is globally asymptotically stable;*
- iii. If $r_1 > c_1 \kappa_2, r_2 > c_2 \kappa_1$, then the unique coexistence equilibrium E^* is globally asymptotically stable.*

The approach of the proof of Theorem 3.1 is mainly to use the comparison principle which is inspired by [63] and the Fluctuation Lemma.

3.3.1 Global Stability of the mono-culture equilibria E_1 and E_2

We shall prove Theorem 3.1 part (i) on the global stability of the mono-culture equilibrium point

$$E_1 = \left(\frac{\delta_1 \kappa_1}{\sigma_1}, \kappa_1, 0, 0 \right)$$

of the system (3.1), in the situation when the other boundary equilibrium

$$E_2 = \left(0, 0, \frac{\delta_2 \kappa_2}{\sigma_2}, \kappa_2 \right)$$

of the system (3.1) is locally unstable. This means that species one out-competes species two in the environment.

Proof of Theorem 3.1 part (i). Let $N_1(t) = (n_d^{(1)}(t), n_b^{(1)}(t))$, $N_2(t) = (n_d^{(2)}(t), n_b^{(2)}(t))$, and $N_B = \left(\frac{\delta_1 \kappa_1}{\sigma_1}, \kappa_1 \right)$ be vectors.

Denote

$$\begin{aligned} \limsup_{t \rightarrow \infty} N_1(t) &= \overline{N_1}, & \liminf_{t \rightarrow \infty} N_1(t) &= \underline{N_1}, \\ \limsup_{t \rightarrow \infty} N_2(t) &= \overline{N_2}, & \liminf_{t \rightarrow \infty} N_2(t) &= \underline{N_2}. \end{aligned}$$

Clearly, $\overline{N_1} \leq N_B$. And by Persistence Theory, $\underline{N_2} \geq 0$.

Let $(n_d^{(2)}(t), n_{b1}^{(2)}(t))$ be the solution of the following system:

$$\begin{aligned} \frac{\partial n_d^{(2)}}{\partial t} &= \delta_2 n_{b1}^{(2)} - \sigma_2 n_d^{(2)} \\ \frac{\partial n_{b1}^{(2)}}{\partial t} &= r_2 n_{b1}^{(2)}(t - \tau_2, x) - \frac{r_2 (n_{b1}^{(2)})^2}{\kappa_2} - \delta_2 n_{b1}^{(2)} + \sigma_2 n_d^{(2)}. \end{aligned} \tag{3.4}$$

Then $\lim_{t \rightarrow \infty} (n_d^{(2)}(t), n_{b1}^{(2)}(t)) = V_1$, where $V_1 = \left(\frac{\delta_2 \kappa_2}{\sigma_2}, \kappa_2 \right)$.

By the Comparison Principle in [44], $\overline{N_2} \leq V_1$.

Let $\epsilon > 0$ be sufficiently small such that $0 < \epsilon < \frac{\kappa_2(r_1 - c_1\kappa_2)}{r_2c_1}$. There exists $t_1 > \tau_2$ such that $N_2 \leq V_1 + \begin{pmatrix} \epsilon \\ \epsilon \end{pmatrix}$ for all $t \geq t_1$ where $\epsilon > 0$ is a sufficiently small number.

Let $(n_d^{(1)}, n_{b1}^{(1)})$ satisfy the following system:

$$\begin{aligned} \frac{\partial n_d^{(1)}}{\partial t} &= \delta_1 n_{b1}^{(1)} - \sigma_1 n_d^{(1)} \\ \frac{\partial n_{b1}^{(1)}}{\partial t} &= r_1 n_{b1}^{(1)}(t - \tau_1, x) - \frac{r_1(n_{b1}^{(1)})^2}{\kappa_1} - \delta_1 n_{b1}^{(1)} + \sigma_1 n_d^{(1)} - c_1 n_{b1}^{(1)}(\kappa_2 + \epsilon). \end{aligned} \quad (3.5)$$

Then $\lim_{t \rightarrow \infty} (n_d^{(1)}(t), n_{b1}^{(1)}(t)) = U_1$, where $U_1 = (\frac{\delta_1 \kappa_1}{\sigma_1}, \frac{\kappa_1[r_1 - c_1(\kappa_2 + \epsilon)]}{r_1})$.

By the positiveness of ϵ and ϵ and Comparison Principle, $\underline{N}_1 \geq U_1$.

Let $\epsilon, \epsilon > 0$, there exists $t_2 > 0$ such that $N_1 \geq U_1 - \begin{pmatrix} \epsilon \\ \epsilon \end{pmatrix}$ for all $t > t_2$.

For $t > t_2$, let $(n_d^{(2)}, n_{b2}^{(2)})$ satisfy the following system:

$$\begin{aligned} \frac{\partial n_d^{(2)}}{\partial t} &= \delta_2 n_{b2}^{(2)} - \sigma_2 n_d^{(2)} \\ \frac{\partial n_{b2}^{(2)}}{\partial t} &= r_2 n_{b2}^{(2)}(t - \tau_2, x) - \frac{r_2(n_{b2}^{(2)})^2}{\kappa_2} - \delta_2 n_{b2}^{(2)} + \sigma_2 n_d^{(2)} - \frac{r_2(U_1^{(2)} - \epsilon)n_{b2}^{(2)}}{\kappa_1}. \end{aligned} \quad (3.6)$$

Since $\frac{\partial n_b^{(2)}}{\partial t} \leq \frac{\partial n_{b2}^{(2)}}{\partial t}$, by the arbitrariness of ϵ and Comparison Principle, $N_2 \leq (n_d^{(2)}, n_{b2}^{(2)})$. Hence $\overline{N}_2 \leq \lim_{t \rightarrow \infty} (n_d^{(2)}(t), n_{b2}^{(2)}(t)) = V_2$, where $V_2 = (\frac{\delta_2 \kappa_2}{\sigma_2}, \kappa_2 - \frac{\kappa_2 U_1^{(2)}}{\kappa_1})$.

Let $\epsilon, \epsilon > 0$, there exists $t_3 > 0$ such that $N_2 \leq V_2 + \begin{pmatrix} \epsilon \\ \epsilon \end{pmatrix}$ for all $t > t_3$. For

$t > t_3$, let $(n_d^{(1)}, n_{b2}^{(1)})$ satisfy the following system:

$$\begin{aligned} \frac{\partial n_d^{(1)}}{\partial t} &= \delta_1 n_{b2}^{(1)} - \sigma_1 n_d^{(1)} \\ \frac{\partial n_{b2}^{(1)}}{\partial t} &= r_1 n_{b2}^{(1)}(t - \tau_1, x) - \frac{r_1(n_{b2}^{(1)})^2}{\kappa_1} - \delta_1 n_{b2}^{(1)} + \sigma_1 n_d^{(1)} - c_1 n_{b2}^{(1)}(V_2^{(2)} + \epsilon). \end{aligned} \quad (3.7)$$

Since $\frac{\partial n_b^{(1)}}{\partial t} \geq \frac{\partial n_{b2}^{(1)}}{\partial t}$, by the arbitrariness of ϵ and Comparison Principle, $\underline{N}_1 \geq (n_d^{(1)}, n_{b2}^{(1)})$. Hence $\underline{N}_1 \geq \lim_{t \rightarrow \infty} (n_d^{(1)}(t), n_{b2}^{(1)}(t)) = U_2$, where $U_2 = (\frac{\delta_1 \kappa_1}{\sigma_1}, \frac{\kappa_1[r_1 - c_1 V_2^{(2)}]}{r_1})$.

Continuing this process, we obtain two vector sequences $\{U_m\}$ and $\{V_m\}$, $m = 1, 2, 3, \dots$ such that for $m \geq 2$,

$$U_m = \left(\frac{\delta_1 \kappa_1}{\sigma_1}, \frac{\kappa_1[r_1 - c_1 V_m^{(2)}]}{r_1} \right)$$

and

$$V_m = \left(\frac{\delta_2 \kappa_2}{\sigma_2}, \frac{\kappa_2 \left[r_2 - \frac{r_2 U_{m-1}^{(2)}}{\kappa_1} \right]}{r_2} \right).$$

Combining the above two equations, we have

$$V_m = \left(\frac{\delta_2 \kappa_2}{\sigma_2}, \frac{\kappa_2 c_1 V_{m-1}^{(2)}}{r_1} \right).$$

Since $\frac{\kappa_2 c_1}{r_1} < 1$,

$$\lim_{m \rightarrow \infty} V_m^{(2)} = 0.$$

Hence,

$$\lim_{m \rightarrow \infty} U_m = N_B.$$

Since the limits of $n_d^{(1)}$, $n_b^{(1)}$, and $n_b^{(2)}$ exist, and $\lim_{t \rightarrow \infty} n_b^{(2)} = 0$, then $\lim_{t \rightarrow \infty} n_d^{(2)} = 0$.

Therefore, $\lim_{t \rightarrow \infty} N_1 = N_B$ and $\lim_{t \rightarrow \infty} N_2 = \mathbf{0}$. We use the notation $\mathbf{0}$ for the constant vector all of whose components are 0. That is,

$$\lim_{t \rightarrow \infty} (n_d^{(1)}(t), n_b^{(1)}(t), n_d^{(2)}(t), n_b^{(2)}(t)) = \left(\frac{\delta_1 \kappa_1}{\sigma_1}, \kappa_1, 0, 0 \right),$$

which completes the proof of Theorem 3.1 part (i). \square

Similarly, we can show that when E_1 is unstable, E_2 is asymptotically stable.

The proof of Theorem 3.1 part (ii) is omitted here.

3.3.2 Global Stability of the coexistence state E^*

In this subsection, we prove Theorem 3.1 part (iii) on the global stability of the coexistence equilibrium

$$E^* = \left(\frac{\delta_1 \kappa_1 r_2 (c_1 \kappa_2 - r_1)}{(c_1 c_2 \kappa_1 \kappa_2 - r_1 r_2) \sigma_1}, \frac{\kappa_1 r_2 (c_1 \kappa_2 - r_1)}{c_1 c_2 \kappa_1 \kappa_2 - r_1 r_2}, \frac{\delta_2 \kappa_2 r_1 (c_2 \kappa_1 - r_2)}{(c_1 c_2 \kappa_1 \kappa_2 - r_1 r_2) \sigma_2}, \frac{\kappa_2 r_1 (c_2 \kappa_1 - r_2)}{c_1 c_2 \kappa_1 \kappa_2 - r_1 r_2} \right)$$

of the system (3.1). We show that when both of the mono-culture equilibria E_1 and E_2 are linearly unstable, the coexistence equilibrium E^* is globally asymptotically stable.

Proof of Theorem 3.1 part (iii). Remark: The notations of N_1 , N_2 , \overline{N}_1 , \underline{N}_1 , \overline{N}_2 , and \underline{N}_2 are defined as same as those in the proof of part (i). To prove this statement, it is equivalent to show that

$$\lim_{t \rightarrow \infty} N_1 = U^*$$

and

$$\lim_{t \rightarrow \infty} N_2 = V^*$$

where

$$U^* = \left(\frac{\delta_1 \kappa_1 r_2 (c_1 \kappa_2 - r_1)}{(c_1 c_2 \kappa_1 \kappa_2 - r_1 r_2) \sigma_1}, \frac{\kappa_1 r_2 (c_1 \kappa_2 - r_1)}{c_1 c_2 \kappa_1 \kappa_2 - r_1 r_2} \right), \quad V^* = \left(\frac{\delta_2 \kappa_2 r_1 (c_2 \kappa_1 - r_2)}{(c_1 c_2 \kappa_1 \kappa_2 - r_1 r_2) \sigma_2}, \frac{\kappa_2 r_1 (c_2 \kappa_1 - r_2)}{c_1 c_2 \kappa_1 \kappa_2 - r_1 r_2} \right)$$

when E_1 and E_2 are both linearly unstable.

Let $\{N_m^u(t)\}$, $\{N_m^v(t)\}$, $\{M_m^u(t)\}$, and $\{M_m^v(t)\}$ be four vector sequences where $m = 1, 2, 3, \dots$. We shall need the above sequences satisfying that

$$M_m^u \leq \underline{N}_1 \leq \overline{N}_1 \leq N_m^u$$

and

$$M_m^v \leq \underline{N}_2 \leq \overline{N}_2 \leq N_m^v.$$

From positivity of solutions we obtain N_1^u as follows:

$$\begin{aligned} \frac{\partial n_d^{(1)}}{\partial t} &= \delta_1 n_b^{(1)} - \sigma_1 n_d^{(1)} \\ \frac{\partial n_b^{(1)}}{\partial t} &\leq r_1 n_b^{(1)}(t - \tau_1, x) - \frac{r_1 (n_b^{(1)})^2}{\kappa_1} - \delta_1 n_b^{(1)} + \sigma_1 n_d^{(1)}. \end{aligned}$$

Hence

$$\overline{N}_1 \leq N_1^u, \text{ where } N_1^u = \left(\frac{\delta_1 \kappa_1}{\sigma_1}, \kappa_1 \right).$$

In a similar way, we have

$$\overline{N}_2 \leq N_1^v, \text{ where } N_1^v = \left(\frac{\delta_2 \kappa_2}{\sigma_2}, \kappa_2 \right).$$

Let $\epsilon, \varepsilon > 0$ be sufficiently small such that $\epsilon < \frac{r_2 - c_2 \kappa_1}{c_2}$. Let $t_1 > 0$ be such that

$$N_1(t) \leq N_1^u + \begin{pmatrix} \varepsilon \\ \epsilon \end{pmatrix} \text{ for all } t \geq t_1.$$

For $t > t_1$, let $m_1^v(t) := \begin{pmatrix} m_1^{v(1)}(t) \\ m_1^{v(2)}(t) \end{pmatrix}$ be a solution of the following system

$$\begin{aligned} \frac{\partial m_1^{v(1)}(t)}{\partial t} &= \delta_2 m_1^{v(2)} - \sigma_2 m_1^{v(1)} \\ \frac{\partial m_1^{v(2)}(t)}{\partial t} &= r_2 m_1^{v(2)}(t - \tau_2, x) - \frac{r_2 (m_1^{v(2)})^2}{\kappa_2} - \delta_2 m_1^{v(2)} + \sigma_2 m_1^{v(1)} - c_2 (N_1^{u(2)} + \epsilon) m_1^{v(2)}, \end{aligned}$$

with appropriate initial data on $[t_1 - \tau_2, t_1]$. Then $\lim_{t \rightarrow \infty} m_1^{v(2)} = \kappa_2 - \frac{\kappa_2 c_2 (N_1^{u(2)} + \epsilon)}{r_2}$.

Since $N_1(t) \leq N_1^u + \begin{pmatrix} \epsilon \\ \epsilon \end{pmatrix}$ for $t \geq t_1$,

$$\frac{\partial N_2(t)}{\partial t} \geq \frac{\partial m_1^v(t)}{\partial t}.$$

So $N_2(t) \geq m_1^v(t)$ and hence

$$\underline{N}_2 \geq \liminf_{t \rightarrow \infty} m_1^v(t) = (v_{l1}, \kappa_2 - \frac{\kappa_2 c_2 (N_1^{u(2)} + \epsilon)}{r_2}), \text{ where } v_{l1} = \liminf_{t \rightarrow \infty} m_1^{v(1)}(t).$$

By the arbitrariness of ϵ , we have

$$\underline{N}_2 \geq M_1^v, \text{ where } M_1^v = (v_{l1}, \kappa_2 - \frac{\kappa_2 c_2 N_1^{u(2)}}{r_2}).$$

With similar argument, we can show that

$$\underline{N}_1 \geq M_1^u, \text{ where } M_1^u = (u_{l1}, \kappa_1 - \frac{\kappa_1 c_1 N_1^{v(2)}}{r_1}) \text{ and } u_{l1} = \liminf_{t \rightarrow \infty} m_1^{u(1)}(t).$$

Let ϵ, ϵ and $t > 0$, there exists $t_2 > 0$ such that $N_2 \geq M_1^v - \begin{pmatrix} \epsilon \\ \epsilon \end{pmatrix}$ for all $t \geq t_2$.

Then for $t > t_2$,

$$\begin{aligned} \frac{\partial n_d^{(1)}(t)}{\partial t} &= \delta_1 n_b^{(1)} - \sigma_1 n_d^{(1)} \\ \frac{\partial n_b^{(1)}(t)}{\partial t} &\leq r_1 n_b^{(1)}(t - \tau_1, x) - \frac{r_1 (n_b^{(1)})^2}{\kappa_1} - \delta_1 n_b^{(1)} + \sigma_1 n_d^{(1)} - c_1 (M_1^{v(2)} - \epsilon) n_b^{(1)}. \end{aligned}$$

Denote $n_2^u(t) = \begin{pmatrix} n_2^{u(1)}(t) \\ n_2^{u(2)}(t) \end{pmatrix}$ as the solution of

$$\begin{aligned} \frac{\partial n_2^{u(1)}(t)}{\partial t} &= \delta_1 n_2^{u(2)}(t) - \sigma_1 n_2^{u(1)}(t) \\ \frac{\partial n_2^{u(2)}(t)}{\partial t} &= r_1 n_2^{u(2)}(t - \tau_1, x) - \frac{r_1 (n_2^{u(2)})^2}{\kappa_1} - \delta_1 n_2^{u(2)} + \sigma_1 n_2^{u(1)} - c_1 (M_1^{v(2)} - \epsilon) n_2^{u(2)}, \end{aligned}$$

for $t > t_2$ with appropriate initial data. Then $N_1(t) \leq n_2^u(t)$ and thus

$$\overline{N_1(t)} \leq \limsup_{t \rightarrow \infty} n_2^u(t) = (u_{u1}, \kappa_1 - \frac{\kappa_1 c_1 (M_1^{v(2)} - \epsilon)}{r_1}), \text{ where } u_{u1} = \limsup_{t \rightarrow \infty} n_2^{u(1)}(t).$$

Since $\epsilon > 0$ is arbitrary,

$$\overline{N_1(t)} \leq N_2^u, \text{ where } N_2^u = (u_{u1}, \kappa_1 - \frac{\kappa_1 c_1 M_1^{v(2)}}{r_1}).$$

Similarly,

$$\overline{N_2(t)} \leq N_2^v, \text{ where } N_2^v = (v_{u1}, \kappa_2 - \frac{\kappa_2 c_2 M_1^{u(2)}}{r_2}) \text{ and } v_{u1} = \limsup_{t \rightarrow \infty} n_2^{v(1)}(t).$$

Now one can show that the transition from the $(m-1)$ th to the m th step in this iterative process is given by

$$\begin{aligned} N_m^{u(2)} &= \kappa_1 - \frac{\kappa_1 c_1 M_{m-1}^{v(2)}}{r_1}, \\ N_m^{v(2)} &= \kappa_2 - \frac{\kappa_2 c_2 M_{m-1}^{u(2)}}{r_2}, \\ M_m^{u(2)} &= \kappa_1 - \frac{\kappa_1 c_1 N_m^{v(2)}}{r_1}, \\ M_m^{v(2)} &= \kappa_2 - \frac{\kappa_2 c_2 N_m^{u(2)}}{r_2}. \end{aligned}$$

Of course, $M_m^u \leq \underline{N_1} \leq \overline{N_1} \leq N_m^u$ and $M_m^v \leq \underline{N_2} \leq \overline{N_2} \leq N_m^v$ for each $m = 1, 2, 3, \dots$

Next we need to show that M_m^u and N_m^u both approach U^* as $m \rightarrow \infty$ and that M_m^v and N_m^v both approach V^* .

Note that

$$N_m^{u(2)} = \kappa_1 - \frac{\kappa_1 \kappa_2 c_1}{r_1} + \frac{\kappa_1 \kappa_2 c_1 c_2 N_{m-1}^{u(2)}}{r_1 r_2}.$$

By the assumption of $r_1 > c_1 \kappa_2$ and $r_2 > c_2 \kappa_1$, we see that $\frac{\kappa_1 \kappa_2 c_1 c_2}{r_1 r_2} < 1$. We claim that $N_m^{u(2)}$ is a monotonically decreasing sequence that is bounded below by $U^{*(2)}$.

We consider

$$\begin{aligned} \frac{N_m^{u(2)}}{N_{m-1}^{u(2)}} &= \frac{\kappa_1 r_1 - \kappa_1 \kappa_2 c_1}{r_1 N_{m-1}^{u(2)}} + \frac{\kappa_1 \kappa_2 c_1 c_2}{r_1 r_2} \\ &\leq \frac{\kappa_1 r_1 - \kappa_1 \kappa_2 c_1}{r_1 U^{*(2)}} + \frac{\kappa_1 \kappa_2 c_1 c_2}{r_1 r_2} \\ &= 1, \end{aligned}$$

so $N_m^{u(2)}$ is monotonically decreasing. Hence $N_m^{u(2)}$ converges to a limit, which is $U^{*(2)}$.

Certainly, convergence of $N_m^{u(2)}$ implies convergence of $M_m^{v(2)}$, and it is easily checked that $M_m^{v(2)}$ has the limit $V^{*(2)}$. The analysis for the remaining two sequences is similar.

Now we have

$$\lim_{t \rightarrow \infty} n_b^{(1)}(t) = \frac{\kappa_1 r_2 (c_1 \kappa_2 - r_1)}{c_1 c_2 \kappa_1 \kappa_2 - r_1 r_2}$$

and

$$\lim_{t \rightarrow \infty} n_b^{(2)}(t) = \frac{\kappa_2 r_1 (c_2 \kappa_1 - r_2)}{c_1 c_2 \kappa_1 \kappa_2 - r_1 r_2}.$$

Since $\lim_{t \rightarrow \infty} \frac{\partial n_d^{(1)}(t)}{\partial t} = 0$ and $\lim_{t \rightarrow \infty} \frac{\partial n_d^{(2)}(t)}{\partial t} = 0$, we have

$$\lim_{t \rightarrow \infty} n_d^{(1)}(t) = \frac{\delta_1 \kappa_1 r_2 (c_1 \kappa_2 - r_1)}{(c_1 c_2 \kappa_1 \kappa_2 - r_1 r_2) \sigma_1}$$

and

$$\lim_{t \rightarrow \infty} n_d^{(2)}(t) = \frac{\delta_2 \kappa_2 r_1 (c_2 \kappa_1 - r_2)}{(c_1 c_2 \kappa_1 \kappa_2 - r_1 r_2) \sigma_2}.$$

The proof of Theorem 3.1 part (iii) is complete. Therefore we complete the proof of Theorem 3.1. \square

By the study of the local and global stability of the equilibria of the non-spatial system (3.1), we conclude that:

1. At least one of the two interactive species with stage structure can persist in a stream due to the fact that the trivial equilibrium E_0 is always unstable.
2. One species out-competes the other one. In other words, one of them will die out due to the competition for the limited resource in the long run.
3. However, under the conditions that the two mono-culture equilibria E_1 and E_2 are both unstable, the two species can coexist and approach a stable population density in long term. This is the explanation of the fact that the

unique coexistence equilibrium E^* is globally asymptotically stable under certain conditions given in Theorem 3.1 part (iii).

CHAPTER 4

EXISTENCE OF TRAVELING WAVES

In this chapter we analyze the spatial system which models spread of two competitive species with stage structure and time delay in a stream subjected to advection and diffusion:

$$\begin{aligned}
\frac{\partial n_d^{(1)}}{\partial t} &= d_1 \frac{\partial^2 n_d^{(1)}}{\partial x^2} - e_1 \frac{\partial n_d^{(1)}}{\partial x} + \delta_1 n_b^{(1)} - \sigma_1 n_d^{(1)} \\
\frac{\partial n_b^{(1)}}{\partial t} &= r_1 n_b^{(1)}(t - \tau_1, x) - \frac{r_1 (n_b^{(1)})^2}{\kappa_1} - \delta_1 n_b^{(1)} + \sigma_1 n_d^{(1)} - c_1 n_b^{(1)} n_b^{(2)} \\
\frac{\partial n_d^{(2)}}{\partial t} &= d_2 \frac{\partial^2 n_d^{(2)}}{\partial x^2} - e_2 \frac{\partial n_d^{(2)}}{\partial x} + \delta_2 n_b^{(2)} - \sigma_2 n_d^{(2)} \\
\frac{\partial n_b^{(2)}}{\partial t} &= r_2 n_b^{(2)}(t - \tau_2, x) - \frac{r_2 (n_b^{(2)})^2}{\kappa_2} - \delta_2 n_b^{(2)} + \sigma_2 n_d^{(2)} - c_2 n_b^{(1)} n_b^{(2)}.
\end{aligned} \tag{4.1}$$

Here $n_d^{(i)}(x, t)$ represents the population density of the i th species in the drift at time t and point x , $n_b^{(i)}(x, t)$ represents the population density of adult members of the i th benthic species at time t and point x , and the description of parameters d_i , e_i , σ_i , δ_i , r_i and β_i can be found in Tables 2.1 and 2.2. This is the system (2.3) which was developed in Chapter 2.

In section 4.1 we define the integral system and show that a traveling wave solution of the delayed reaction-diffusion system is equivalent to a fixed point of a compact integral operator. In section 4.2 we prove that via integral systems there exist traveling wave solutions with speeds above two extended real numbers.

4.1 Integral System

Assume $E_1 = (\frac{\delta_1 \kappa_1}{\sigma_1}, \kappa_1, 0, 0)$ is unstable, i.e., $r_2 > c_2 \kappa_1$.

Let $n_d^{(1)} := \frac{\delta_1 \kappa_1}{\sigma_1} - n_d^{(1)}$ and $n_b^{(1)} := \kappa_1 - n_b^{(1)}$. We convert the competition

system (4.1) into the following cooperative system:

$$\begin{aligned}
\frac{\partial n_d^{(1)}}{\partial t} &= d_1 \frac{\partial^2 n_d^{(1)}}{\partial x^2} - e_1 \frac{\partial n_d^{(1)}}{\partial x} + \delta_1 n_b^{(1)} - \sigma_1 n_d^{(1)} \\
\frac{\partial n_b^{(1)}}{\partial t} &= r_1 n_b^{(1)} (t - \tau_1, x) + \frac{r_1 (n_b^{(1)})^2}{\kappa_1} - 2r_1 n_b^{(1)} - \delta_1 n_b^{(1)} + \sigma_1 n_d^{(1)} - c_1 n_b^{(1)} n_b^{(2)} + c_1 \kappa_1 n_b^{(2)} \\
\frac{\partial n_d^{(2)}}{\partial t} &= d_2 \frac{\partial^2 n_d^{(2)}}{\partial x^2} - e_2 \frac{\partial n_d^{(2)}}{\partial x} + \delta_2 n_b^{(2)} - \sigma_2 n_d^{(2)} \\
\frac{\partial n_b^{(2)}}{\partial t} &= r_2 n_b^{(2)} (t - \tau_2, x) - \frac{r_2 (n_b^{(2)})^2}{\kappa_2} - \delta_2 n_b^{(2)} + \sigma_2 n_d^{(2)} + c_2 n_b^{(1)} n_b^{(2)} - c_2 \kappa_1 n_b^{(2)}.
\end{aligned} \tag{4.2}$$

For this system, we denote

$$\boldsymbol{\beta} = \left(\frac{\delta_1 \kappa_1}{\sigma_1}, \kappa_1, \frac{\delta_2 \kappa_2}{\sigma_2}, \kappa_2 \right) \tag{4.3}$$

and notice that $\mathbf{0} = (0, 0, 0, 0)$ and $\boldsymbol{\beta}$ are equilibria of the cooperative system (4.2).

We denote the system (4.2) in a more general form of

$$\frac{\partial \mathbf{u}}{\partial t} = \mathbf{D} \frac{\partial^2 \mathbf{u}}{\partial x^2} - \mathbf{E} \frac{\partial \mathbf{u}}{\partial x} + \mathbf{f}(\mathbf{u}(\theta, \mathbf{t}, \mathbf{x})) \tag{4.4}$$

where $\mathbf{D} = \text{diag}\{d_1, 0, d_2, 0\}$, $\mathbf{E} = \text{diag}\{e_1, 0, e_2, 0\}$,

$$\mathbf{f}(\mathbf{u}(\theta, t, x)) = \begin{pmatrix} \delta_1 u_2 - \sigma_1 u_1 \\ r_1 u_2 (t - \tau_1, x) + \frac{r_1 u_2^2}{\kappa_1} - 2r_1 u_2 - \delta_1 u_2 + \sigma_1 u_1 - c_1 u_2 u_4 + c_1 \kappa_1 u_4 \\ \delta_2 u_4 - \sigma_2 u_3 \\ r_2 u_4 (t - \tau_2, x) - \frac{r_2 u_4^2}{\kappa_2} - \delta_2 u_4 + \sigma_2 u_3 + c_2 u_2 u_4 - c_2 \kappa_1 u_4, \end{pmatrix}$$

and $\mathbf{u} := (u_1, u_2, u_3, u_4) = (n_d^{(1)}, n_b^{(1)}, n_d^{(2)}, n_b^{(2)})$. Here, θ appearing in the function $\mathbf{f}(\mathbf{u}(\theta, t, x))$ represents the presence of time delays involved in the growth and spread of the population. We use the notation

$$\mathcal{C}_{\boldsymbol{\beta}} := \{\mathbf{u} : \mathbf{u}(x) \text{ is continuous, and } \mathbf{0} \leq \mathbf{u}(x) \leq \boldsymbol{\beta} \text{ for all } x\}. \tag{4.5}$$

We are interested in a nonincreasing traveling wave solution $\mathbf{w}(c; \theta, x - ct) = (\phi_d(\theta_1, x - ct), \phi_b(\theta_2, x - ct), \psi_d(\theta_3, x - ct), \psi_b(\theta_4, x - ct))$ of our cooperative system (4.2) with speed c connecting the equilibria $\mathbf{0}$ and $\boldsymbol{\beta}$.

Let $\xi = x - ct$. The wave equation of the cooperative system (4.2) is

$$\begin{aligned}
d_1\phi_d''(\xi) + (c - e_1)\phi_d'(\xi) + \delta_1\phi_b(\xi) - \sigma_1\phi_d(\xi) &= 0 \\
c\phi_b'(\xi) + r_1\phi_b(\xi - c\tau_1) + \frac{r_1(\phi_b(\xi))^2}{\kappa_1} - 2r_1\phi_b(\xi) - \delta_1\phi_b(\xi) + \sigma_1\phi_d(\xi) - c_1\phi_b(\xi)\psi_b(\xi) + c_1\kappa_1\psi_b(\xi) &= 0 \\
d_2\psi_d''(\xi) + (c - e_2)\psi_d'(\xi) + \delta_2\psi_b(\xi) - \sigma_2\psi_d(\xi) &= 0 \\
c\psi_b'(\xi) + r_2\psi_b(\xi - c\tau_2) - \frac{r_2(\psi_b(\xi))^2}{\kappa_2} - \delta_2\psi_b(\xi) + \sigma_2\psi_d(\xi) + c_2\phi_b(\xi)\psi_b(\xi) - c_2\kappa_1\psi_b(\xi) &= 0,
\end{aligned} \tag{4.6}$$

with $\lim_{\xi \rightarrow -\infty} \mathbf{w}(\xi) = \mathbf{0}$ and $\lim_{\xi \rightarrow \infty} \mathbf{w}(\xi) = \boldsymbol{\beta}$.

Since some diffusion coefficients $d_i = 0$ in the cooperative system (4.2), the compactness of solution operators cannot be guaranteed. Therefore we shall work on the integral equation corresponding to the cooperative system (4.2) in order to prove the existence of traveling wave solutions.

$$\text{Choose } \kappa > 0. \text{ Define } \mathbf{H}_1(\mathbf{u})(\xi) = \frac{1}{\kappa} \begin{pmatrix} 0 \\ r_1u_2(\xi) \\ 0 \\ 0 \end{pmatrix}, \mathbf{H}_2(\mathbf{u})(\xi) = \frac{1}{\kappa} \begin{pmatrix} 0 \\ 0 \\ 0 \\ r_2u_4(\xi) \end{pmatrix},$$

and $\mathbf{H}_3(\mathbf{u}) = (\tilde{\mathbf{f}}(\mathbf{u}) + \kappa\mathbf{u})\frac{1}{\kappa}$ where

$$\tilde{\mathbf{f}}(\mathbf{u}(t, x)) = \begin{pmatrix} \delta_1u_2 - \sigma_1u_1 \\ \frac{r_1u_2^2}{\kappa_1} - 2r_1u_2 - \delta_1u_2 + \sigma_1u_1 - c_1u_2u_4 + c_1\kappa_1u_4 \\ \delta_2u_4 - \sigma_2u_3 \\ -\frac{r_2u_4^2}{\kappa_2} - \delta_2u_4 + \sigma_2u_3 + c_2u_2u_4 - c_2\kappa_1u_4 \end{pmatrix}.$$

There is a proper subset Σ_0 of $\{1, \dots, k\}$ such that $d_i = 0$ for $i \in \Sigma_0$ and $d_i > 0$ for $i \notin \Sigma_0$. For $i \in \Sigma_0$, if $c > 0$, define

$$(\mathbf{m}_c)_i(x) = \begin{cases} 0 & \text{when } x > 0, \\ \frac{\kappa}{c}e^{\frac{\kappa}{c}x} & \text{when } x \leq 0, \end{cases}$$

and if $c < 0$, define

$$(\mathbf{m}_c)_i(x) = \begin{cases} \frac{\kappa}{-c}e^{\frac{\kappa}{c}x} & \text{when } x \geq 0, \\ 0 & \text{when } x < 0. \end{cases}$$

For $i \notin \Sigma_0$, define

$$(\mathbf{m}_c)_i(x) = \frac{\kappa}{d_i(\lambda_{i1} - \lambda_{i2})} \begin{cases} e^{-\lambda_{i1}x} & \text{when } x \geq 0, \\ e^{-\lambda_{i2}x} & \text{when } x < 0, \end{cases}$$

where

$$\begin{aligned} \lambda_{i1} &= \frac{(c-e_i) + \sqrt{(c-e_i)^2 + 4\kappa d_i}}{2d_i} > 0, \\ \lambda_{i2} &= \frac{(c-e_i) - \sqrt{(c-e_i)^2 + 4\kappa d_i}}{2d_i} < 0. \end{aligned}$$

Let

$$\mathbf{m}_c(x) = \text{diag}((\mathbf{m}_c)_1(x), \dots, (\mathbf{m}_c)_k(x)).$$

We have that

$$\int_{-\infty}^{\infty} \mathbf{m}_c(x) dx = \mathbf{I}.$$

Wu and Zou [69] used $(\mathbf{m}_c)_i$ defined above and studied traveling wave solutions for delayed reaction-diffusion systems with $d_i > 0$ and $e_i = 0$ for all i . Li [53] introduced the function similar to $(\mathbf{m}_c)_i$ and investigated the existence of traveling wave solutions for the cooperative reaction-diffusion system without time delay.

It is easy to verify that each $(\mathbf{m}_c)_i(x)$ defined above has the properties that $(\mathbf{m}_c)_i(x) \geq 0$, $(\mathbf{m}_c)_i(x)$ is bounded, and $\int_{-\infty}^{+\infty} (\mathbf{m}_c)_i(x) dx = 1$, so that $(\mathbf{m}_c)_i(x)$ represents a probability density function.

Define the integral system

$$T_c[\mathbf{u}](x) = \int_{-\infty}^{\infty} [\mathbf{m}_c(x + c\tau_1 - y)\mathbf{H}_1(\mathbf{u})(y) + \mathbf{m}_c(x + c\tau_2 - y)\mathbf{H}_2(\mathbf{u})(y) + \mathbf{m}_c(x - y)\mathbf{H}_3(\mathbf{u})(y)] dy. \quad (4.7)$$

We shall consider the integral system (4.7) in the proof of traveling wave solution.

THEOREM 4.1. *Assume that $d_i \geq 0$ for all i . Let $c \neq 0$ for all i with $d_i = 0$. Then $\mathbf{w}(x - ct)$ is a nonincreasing traveling wave solution of (4.2) connecting two different constant equilibria $\mathbf{0}$ and β if and only if \mathbf{w} is a continuous nonincreasing function satisfying*

$$\mathbf{w} = T_c[\mathbf{w}](x)$$

and connecting $\mathbf{0}$ and β .

The proof of Theorem 4.1 is similar to the proof of Theorem 3.1 in [53], we thus omit the proof here. This theorem demonstrates that a traveling wave solution of the system (4.2) is equivalent to a fixed point of an operator of the compact integral system (4.7).

4.2 Traveling Wave Solutions

In this section we prove the existence of traveling wave solutions for the cooperative system (4.2). The next theorem gives us the important connection between traveling wave solutions of the cooperative system (4.2) and those of the integral system (4.7).

Define

$$\mathbf{D}^{(l)} = \mathbf{D} + \left(\frac{1}{l}\right)\mathbf{I}$$

with $l \geq 1$ and \mathbf{I} the 4×4 identity matrix. Clearly, $\mathbf{D}^{(l)}$ approaches \mathbf{D} as $l \rightarrow \infty$. And the solution map operators for

$$\frac{\partial \mathbf{u}}{\partial t} = \mathbf{D}^{(l)} \frac{\partial^2 \mathbf{u}}{\partial x^2} - \mathbf{E} \frac{\partial \mathbf{u}}{\partial x} + \mathbf{f}(\mathbf{u}(\mathbf{t} - \tau, \mathbf{x})) \quad (4.8)$$

are compact.

4.2.1 Recursions With Delay

We use \mathcal{H} to denote the habitat where the species grow, interact and migrate. \mathcal{H} is either the real line (the continuous habitat) or the subset of the real line which consist of all integral multiples of positive mesh size h (a discrete habitat). Let τ be a nonnegative real number. We use boldface Roman symbols such as $\mathbf{u}(\theta, x)$ to denote k -vector-valued functions of the two variables θ and x , and

boldface Greek letters to stand for k -vectors, which may be considered as constant vector-valued functions. Here, $\mathbf{u} \geq \mathbf{v}$ means that $u^i(\theta, x) \geq v^i(\theta, x)$ for all $i = 1, 2, \dots, k$, $\theta \in [-\tau, 0]$ and $x \in \mathcal{H}$, and $\mathbf{u} \gg \mathbf{v}$ means that $u^i(\theta, x) > v^i(\theta, x)$ for all i , θ and x . We also define $\max\{\mathbf{u}(\theta, x), \mathbf{v}(\theta, x)\}$ as the vector-valued function whose i th component at (θ, x) is $\max\{u^i(\theta, x), v^i(\theta, x)\}$.

Let \mathcal{C} be the set of all bounded continuous functions from $[-\tau, 0] \times \mathcal{H}$ to \mathbb{R}^k , $\bar{\mathcal{C}}$ be the set of all bounded continuous functions from $[-\tau, 0]$ to \mathbb{R}^k , and \mathcal{X} be the set of bounded continuous functions from \mathcal{H} to \mathbb{R}^k . If $\mathbf{r} \in \bar{\mathcal{C}}$ with $\mathbf{r} \gg \mathbf{0}$, we define the set of continuous functions

$$\mathcal{C}_{\mathbf{r}} := \{\mathbf{u} \in \mathcal{C} : \mathbf{0} \leq \mathbf{u} \leq \mathbf{r}\}.$$

Moreover, we define the metric function $d(\cdot, \cdot)$ in \mathcal{C} by

$$d(\phi, \psi) = \sum_{k=0}^{\infty} \frac{\max_{|x| \leq k, \theta \in [-\tau, 0]} |\phi(\theta, \mathbf{x}) - \psi(\theta, \mathbf{x})|}{2^k} \quad \forall \phi, \psi \in \mathcal{C} \quad (4.9)$$

so that (\mathcal{C}, d) is a metric space. The convergence of a sequence ϕ_n to ϕ with respect to this topology is equivalent to the uniform convergence of $\phi_{\mathbf{n}}$ to ϕ on bounded subsets of $[-\tau, 0] \times \mathcal{H}$.

We study the following discrete-time recursion with delay:

$$\mathbf{u}_{n+1} = Q[\mathbf{u}_n], \quad n = 0, 1, 2, \dots \quad (4.10)$$

where $\mathbf{u}_n(\theta, x) = (u_n^1(\theta, x), u_n^2(\theta, x), \dots, u_n^k(\theta, x))$, $\theta \in [-\tau, 0]$, and $x \in \mathcal{H}$ represents the population densities of k species at time n and point x with time delay τ . The operator Q is said to be **order – preserving** if $\mathbf{u} \geq \mathbf{v}$ implies that $Q[\mathbf{u}] \geq Q[\mathbf{v}]$. A recursion (4.10) in which Q has this property is said to be **cooperative**. A function is said to be an equilibrium of Q if $Q[\mathbf{w}] = \mathbf{w}$, so that if $\mathbf{u}_l = \mathbf{w}$ in the recursion (4.10), then $\mathbf{u}_n = \mathbf{w}$ for all $n \geq l$. We shall study the evolution of the solution \mathbf{u}_n of the recursion (4.10) from a \mathbf{u}_0 near an unstable constant equilibrium

θ . By introducing the new variable $\hat{\mathbf{u}} = \mathbf{u} - \theta$ if necessary, we shall assume the unstable equilibrium θ from which the system moves away is the origin $\mathbf{0}$.

We define the translation operator

$$T_y[\mathbf{v}](\theta, x) = \mathbf{v}(\theta, x - y).$$

A set $D \in \mathcal{C}_r$ is said to be T -invariant if $T_y[D] = D$ for any $y \in \mathcal{H}$.

We shall make the following hypotheses on Q .

HYPOTHESES 4.1.

- i.* $Q[\mathbf{0}] = \mathbf{0}$, and there is a vector $\beta(\theta) \in \bar{\mathcal{C}}$ with $\beta(\theta) \gg \mathbf{0}$ such that $Q[\beta] = \beta$, and if \mathbf{u}_0 is any vector in $\bar{\mathcal{C}}$ with $\beta(\theta) \gg \mathbf{u}_0 \gg \mathbf{0}$, then the vector-valued function \mathbf{u}_n obtained from the recursion (4.10) converges to $\beta(\theta)$ uniformly on $[-\tau, 0]$ as n approaches infinity.
- ii.* Q is order-preserving on nonnegative functions, so that if $\mathbf{u} \geq \mathbf{v} \geq \mathbf{0}$, then $Q[\mathbf{u}] \geq Q[\mathbf{v}] \geq \mathbf{0}$.
- iii.* Q is translation invariant so that $Q[T_y[\mathbf{v}]] = T_y[Q[\mathbf{v}]]$ for all y .
- iv.* Q is continuous with respect to the topology determined by $d(\cdot, \cdot)$ given in (4.9).
- v.* One of the following two properties holds:
 - a.* $Q[\mathcal{C}_\beta]$ is precompact in \mathcal{C}_β .
 - b.* The set $Q[\mathcal{C}_\beta](0, \cdot)$ is precompact in \mathcal{X} , and there is a positive number $\zeta \leq \tau$ such that $Q[\mathbf{u}](\theta, x) = \mathbf{u}(\theta + \zeta, x)$ for all $\theta \in [-\tau, -\zeta]$, and the operator

$$S[\mathbf{u}](\theta, x) = \begin{cases} \mathbf{u}(0, x), & \theta \in [-\tau, -\zeta), \\ Q[\mathbf{u}](\theta, x), & \theta \in [-\zeta, 0], \end{cases}$$

has the property that $S[D]$ is precompact in \mathcal{C}_β for any T -invariant set $D \in \mathcal{C}_\beta$ with $D(0, \cdot)$ precompact in \mathcal{X} .

Hypotheses 4.1 represents a revised set of the hypotheses given in [67].

REMARK 4.1. *Hypotheses 4.1 i-ii imply that Q takes \mathcal{C}_β into itself, and that the equilibrium β attracts all initial functions in \mathcal{C}_β with uniformly positive components. In biological terms, β is a globally asymptotically stable coexistence equilibrium. There may also be other equilibria lying between β and the extinction equilibrium $\mathbf{0}$, in each of which at least one of the species is extinct. In this paper, we assume that the recursion (4.10) has a finite number of equilibria and that the equilibria of (4.10) are completely separate in the sense that for any two equilibria $\nu_1(\theta), \nu_2(\theta) \in \bar{\mathcal{C}}$ of (4.10), if $\nu_1^i(\theta) \neq \nu_2^i(\theta)$ for some $\theta \in [-\tau, 0]$, then $\nu_1^i(\theta) \neq \nu_2^i(\theta)$ for all $\theta \in [-\tau, 0]$.*

REMARK 4.2. *Li and Zhang [62] proposed the very similar hypotheses for their delayed cooperative systems. The difference between our system and theirs is that we divide each species into two compartments which results in the formation of two reaction-diffusion equations and two ordinary differential equations in our model. But those hypotheses given in [62] for the solution operator Q can be applied for our model.*

Before proving the existence of traveling wave solution of the system (4.2), we give the following lemma which is applied in our discussion and can be found in [52, 67, 68].

LEMMA 4.1. *(Comparison Lemma). Let R be an order preserving operator. If \mathbf{u}_n and \mathbf{v}_n satisfy the inequalities $\mathbf{u}_n \leq R[\mathbf{u}_n]$ and $\mathbf{v}_n \geq R[\mathbf{v}_n]$ for all n , and if $\mathbf{u}_0 \leq \mathbf{v}_0$, then $\mathbf{u}_n \leq \mathbf{v}_n$ for all n .*

4.2.2 Existence of Traveling Wave Solutions

Next, we prove the existence of traveling wave solutions of system (4.2). Our methods and arguments are highly inspired by the earlier works in [53, 67]. However, our extended model is nontrivial and needs some new ideas and techniques such as taking the limit of a sequence of functions that are fixed points of the integral system.

Recall the cooperative system (4.2),

$$\begin{aligned}\frac{\partial n_d^{(1)}}{\partial t} &= d_1 \frac{\partial^2 n_d^{(1)}}{\partial x^2} - e_1 \frac{\partial n_d^{(1)}}{\partial x} + \delta_1 n_b^{(1)} - \sigma_1 n_d^{(1)} \\ \frac{\partial n_b^{(1)}}{\partial t} &= r_1 n_b^{(1)}(t - \tau_1, x) + \frac{r_1 (n_b^{(1)})^2}{\kappa_1} - 2r_1 n_b^{(1)} - \delta_1 n_b^{(1)} + \sigma_1 n_d^{(1)} - c_1 n_b^{(1)} n_b^{(2)} + c_1 \kappa_1 n_b^{(2)} \\ \frac{\partial n_d^{(2)}}{\partial t} &= d_2 \frac{\partial^2 n_d^{(2)}}{\partial x^2} - e_2 \frac{\partial n_d^{(2)}}{\partial x} + \delta_2 n_b^{(2)} - \sigma_2 n_d^{(2)} \\ \frac{\partial n_b^{(2)}}{\partial t} &= r_2 n_b^{(2)}(t - \tau_2, x) - \frac{r_2 (n_b^{(2)})^2}{\kappa_2} - \delta_2 n_b^{(2)} + \sigma_2 n_d^{(2)} + c_2 n_b^{(1)} n_b^{(2)} - c_2 \kappa_1 n_b^{(2)},\end{aligned}$$

where $\mathbf{0} = (0, 0, 0, 0)$ and $\boldsymbol{\beta} = (\frac{\delta_1 \kappa_1}{\sigma_1}, \kappa_1, \frac{\delta_2 \kappa_2}{\sigma_2}, \kappa_2)$ are the only two equilibria in \mathcal{C}_β when $r_2 > c_2 \kappa_1$, and the compact system (4.8)

$$\frac{\partial \mathbf{u}}{\partial t} = \mathbf{D}^{(l)} \frac{\partial^2 \mathbf{u}}{\partial x^2} - \mathbf{E} \frac{\partial \mathbf{u}}{\partial x} + \mathbf{f}(\mathbf{u}(\mathbf{t} - \tau, \mathbf{x})).$$

DEFINITION 1. A function $(u_d(t, x), u_b(t, x), v_d(t, x), v_b(t, x)) : [-\tau, b) \times \mathbb{R} \rightarrow \mathbb{R}^4$, $b > 0$, with the properties that (u_d, u_b, v_d, v_b) is \mathbf{C}^2 in $x \in \mathbb{R}$ and \mathbf{C}^1 in $t \in (0, b)$ is called a super-solution (sub-solution) of (4.8) on $[0, b)$ if for $t \in [0, b)$, $x \in \mathbb{R}$

$$\begin{aligned}\frac{\partial u_d}{\partial t} &\geq (\leq) d_{u_d} \frac{\partial^2 u_d}{\partial x^2} - e_1 \frac{\partial u_d}{\partial x} + \delta_1 u_b - \sigma_1 u_d \\ \frac{\partial u_b}{\partial t} &\geq (\leq) d_{u_b} \frac{\partial^2 u_b}{\partial x^2} + r_1 u_b(t - \tau_1, x) + \frac{r_1 (u_b)^2}{\kappa_1} - 2r_1 u_b - \delta_1 u_b + \sigma_1 u_d - c_1 u_b v_b + c_1 \kappa_1 v_b \\ \frac{\partial v_d}{\partial t} &\geq (\leq) d_{v_d} \frac{\partial^2 v_d}{\partial x^2} - e_2 \frac{\partial v_d}{\partial x} + \delta_2 v_b - \sigma_2 v_d \\ \frac{\partial v_b}{\partial t} &\geq (\leq) d_{v_b} \frac{\partial^2 v_b}{\partial x^2} + r_2 v_b(t - \tau_2, x) - \frac{r_2 (v_b)^2}{\kappa_2} - \delta_2 v_b + \sigma_2 v_d + c_2 u_b v_b - c_2 \kappa_1 v_b.\end{aligned}$$

LEMMA 4.2. For any $(\phi_d, \phi_b, \psi_d, \psi_b) \in \mathcal{C}_\beta$, system (4.8) has a unique classical solution

$(u_d(t, x; \phi_d, \phi_b, \psi_d, \psi_b), u_b(t, x; \phi_d, \phi_b, \psi_d, \psi_b), v_d(t, x; \phi_d, \phi_b, \psi_d, \psi_b), v_b(t, x; \phi_d, \phi_b, \psi_d, \psi_b))$
for $(t, x) \in [\tau, \infty) \times \mathbb{R}$, where $(u_d(0, x), u_b(0, x), v_d(0, x), v_b(0, x)) = (\phi_d, \phi_b, \psi_d, \psi_b)$.

Furthermore, for any pair of super-solution $(\bar{u}_d(t, x), \bar{u}_b(t, x), \bar{v}_d(t, x), \bar{v}_b(t, x))$ and sub-solution $(\underline{u}_d(t, x), \underline{u}_b(t, x), \underline{v}_d(t, x), \underline{v}_b(t, x))$ of (4.8) with

$$\begin{aligned} \mathbf{0} = (0, 0, 0, 0) &\leq (\underline{u}_d(t, x), \underline{u}_b(t, x), \underline{v}_d(t, x), \underline{v}_b(t, x)) \\ &\leq (\bar{u}_d(t, x), \bar{u}_b(t, x), \bar{v}_d(t, x), \bar{v}_b(t, x)) \\ &\leq \left(\frac{\delta_1 \kappa_1}{\sigma_1}, \kappa_1, \frac{\delta_2 \kappa_2}{\sigma_2}, \kappa_2 \right) = \boldsymbol{\beta} \end{aligned}$$

for $t \in [-\tau, 0]$ and $x \in \mathbb{R}$, the above compound inequality holds for $t \geq 0$ and $x \in \mathbb{R}$.

Proof. Define $f_i : \mathcal{C} \times \mathcal{C} \rightarrow \mathcal{X}$, $i = 1, 2, 3, 4$, by

$$\begin{aligned} f_1(\phi_d, \phi_b, \psi_d, \psi_b)(x) &= \delta_1 \phi_b(0, x) - \sigma_1 \phi_d(0, x) \\ f_2(\phi_d, \phi_b, \psi_d, \psi_b)(x) &= r_1 \phi_b(-\tau_1, x) + \frac{r_1 \phi_b^2(0, x)}{\kappa_1} - 2r_1 \phi_b(0, x) - \delta_1 \phi_b(0, x) \\ &\quad + \sigma_1 \phi_d(0, x) - c_1 \phi_b(0, x) \psi_b(0, x) + c_1 \kappa_1 \psi_b(0, x) \\ f_3(\phi_d, \phi_b, \psi_d, \psi_b)(x) &= \delta_2 \psi_b(0, x) - \sigma_2 \psi_d(0, x) \\ f_4(\phi_d, \phi_b, \psi_d, \psi_b)(x) &= r_2 \psi_b(-\tau_2, x) - \frac{r_2 \psi_b^2(0, x)}{\kappa_2} - \delta_2 \psi_b(0, x) + \sigma_2 \psi_d(0, x) \\ &\quad + c_2 \phi_b(0, x) \psi_b(0, x) - c_2 \kappa_1 \psi_b(0, x). \end{aligned} \tag{4.11}$$

The system (4.8) can be rewritten as

$$\begin{aligned} \frac{\partial u_d}{\partial t} &= d_{u_d} \frac{\partial^2 u_d}{\partial x^2} - e_1 \frac{\partial u_d}{\partial x} + f_1(u_{dt}, u_{bt}, v_{dt}, v_{bt})(x) \\ \frac{\partial u_b}{\partial t} &= d_{u_b} \frac{\partial^2 u_b}{\partial x^2} + f_2(u_{dt}, u_{bt}, v_{dt}, v_{bt})(x) \\ \frac{\partial v_d}{\partial t} &= d_{v_d} \frac{\partial^2 v_d}{\partial x^2} - e_2 \frac{\partial v_d}{\partial x} + f_3(u_{dt}, u_{bt}, v_{dt}, v_{bt})(x) \\ \frac{\partial v_b}{\partial t} &= d_{v_b} \frac{\partial^2 v_b}{\partial x^2} + f_4(u_{dt}, u_{bt}, v_{dt}, v_{bt})(x), \end{aligned} \tag{4.12}$$

$t > 0, x \in \mathbb{R}$,

where $u_{dt}, u_{bt}, v_{dt}, v_{bt} \in \mathcal{C}$ with $u_{dt}(\theta, x) = u_d(t + \theta, x)$, $u_{bt}(\theta, x) = u_b(t + \theta, x)$, $v_{dt}(\theta, x) = v_d(t + \theta, x)$ and $v_{bt}(\theta, x) = v_b(t + \theta, x)$ for $\theta \in [-\tau, 0]$, $x \in \mathbb{R}$.

Let $\{T_{u_d}(t)\}_{t \geq 0}$, $\{S_{u_b}(t)\}_{t \geq 0}$, $\{T_{v_d}(t)\}_{t \geq 0}$ and $\{S_{v_b}(t)\}_{t \geq 0}$ be the solution

semigroup on \mathcal{X} generated by the heat equations

$$\begin{aligned} u_{d,t} &= d_{u_d} \Delta u_d - e_1 u_{d,x}, \\ u_{b,t} &= d_{u_b} \Delta u_b, \\ v_{d,t} &= d_{v_d} \Delta v_d - e_2 v_{d,x}, \quad \text{and} \\ v_{b,t} &= d_{v_b} \Delta v_b. \end{aligned}$$

Then we can write (4.12) as the following integral equations:

$$\begin{aligned} u_d(t, x) &= T_{u_d}(t)u_d(0, \cdot)(x) + \int_0^t T_{u_d}(t-s)f_1(u_{dt}, u_{bt}, v_{dt}, v_{bt})(x)ds \\ u_b(t, x) &= S_{u_b}(t)u_b(0, \cdot)(x) + \int_0^t S_{u_b}(t-s)f_2(u_{dt}, u_{bt}, v_{dt}, v_{bt})(x)ds \\ v_d(t, x) &= T_{v_d}(t)v_d(0, \cdot)(x) + \int_0^t T_{v_d}(t-s)f_3(u_{dt}, u_{bt}, v_{dt}, v_{bt})(x)ds \\ v_b(t, x) &= S_{v_b}(t)v_b(0, \cdot)(x) + \int_0^t S_{v_b}(t-s)f_4(u_{dt}, u_{bt}, v_{dt}, v_{bt})(x)ds, \quad t > 0 \end{aligned} \tag{4.13}$$

where

$$\begin{aligned} T_{u_d}(t) &= \frac{1}{\sqrt{4\pi d_{u_d} t}} \int_{-\infty}^{\infty} e^{-\frac{[(y-x)+e_1 t]^2}{4d_{u_d} t}} dy, \\ S_{u_b}(t) &= \frac{1}{\sqrt{4\pi d_{u_b} t}} \int_{-\infty}^{\infty} e^{-\frac{(y-x)^2}{4d_{u_b} t}} dy, \\ T_{v_d}(t) &= \frac{1}{\sqrt{4\pi d_{v_d} t}} \int_{-\infty}^{\infty} e^{-\frac{[(y-x)+e_2 t]^2}{4d_{v_d} t}} dy, \\ S_{v_b}(t) &= \frac{1}{\sqrt{4\pi d_{v_b} t}} \int_{-\infty}^{\infty} e^{-\frac{(y-x)^2}{4d_{v_b} t}} dy. \end{aligned}$$

Under the abstract setting in Martin and Smith, a mild solution of (4.12) is a solution to its associated integral equation (4.13). One can easily verify that f_i , $i = 1, 2, 3, 4$ are Lipschitz continuous on any bounded subset of $\mathcal{C} \times \mathcal{C}$. Let $\mathcal{Z} = \mathbf{BUC}(\mathbb{R}, \mathbb{R}^4)$ be the Banach space of all bounded and uniformly continuous functions from \mathbb{R} into \mathbb{R}^4 with the usual supremum norm. Let $\mathcal{Z}^+ = \{(\phi_{d1}, \phi_{d2}) : (\phi_{d1}, \phi_{d2}) \in \mathcal{Z}, \phi_{di}(x) \geq 0, i = 1, 2\}$. We claim that f_i , $i = 1, 2, 3, 4$ are quasi-

monotone on \mathcal{C} in the sense that

$$\begin{aligned}
\lim_{h \rightarrow 0^+} \frac{1}{h} \text{dist}(\phi_{d2}(0) - \phi_{d1}(0) + h[f_1(\phi_{d2}, \phi_{b2}, \psi_{d2}, \psi_{b2}) - f_1(\phi_{d1}, \phi_{b1}, \psi_{d1}, \psi_{b1})]; \mathcal{Z}^+) &= 0 \\
\lim_{h \rightarrow 0^+} \frac{1}{h} \text{dist}(\phi_{b2}(0) - \phi_{b1}(0) + h[f_2(\phi_{d2}, \phi_{b2}, \psi_{d2}, \psi_{b2}) - f_2(\phi_{d1}, \phi_{b1}, \psi_{d1}, \psi_{b1})]; \mathcal{Z}^+) &= 0 \\
\lim_{h \rightarrow 0^+} \frac{1}{h} \text{dist}(\psi_{d2}(0) - \psi_{d1}(0) + h[f_3(\phi_{d2}, \phi_{b2}, \psi_{d2}, \psi_{b2}) - f_3(\phi_{d1}, \phi_{b1}, \psi_{d1}, \psi_{b1})]; \mathcal{Z}^+) &= 0 \\
\lim_{h \rightarrow 0^+} \frac{1}{h} \text{dist}(\psi_{b2}(0) - \psi_{b1}(0) + h[f_4(\phi_{d2}, \phi_{b2}, \psi_{d2}, \psi_{b2}) - f_4(\phi_{d1}, \phi_{b1}, \psi_{d1}, \psi_{b1})]; \mathcal{Z}^+) &= 0,
\end{aligned} \tag{4.14}$$

for all $\phi_{dj}, \phi_{bj}, \psi_{dj}, \psi_{bj} \in \mathcal{C}_\beta$ for $j = 1, 2$ with $(\phi_{d2}, \phi_{b2}, \psi_{d2}, \psi_{b2}) \geq (\phi_{d1}, \phi_{b1}, \psi_{d1}, \psi_{b1})$.

From the definitions of f_i , $i = 1, 2, 3, 4$ in (7.1) we see that

$$\begin{aligned}
f_1(\phi_{d2}, \phi_{b2}, \psi_{d2}, \psi_{b2}) &- f_1(\phi_{d1}, \phi_{b1}, \psi_{d1}, \psi_{b1}) \\
&= \delta_1 \phi_{b2}(0, x) - \sigma_1 \phi_{d2}(0, x) - (\delta_1 \phi_{b1}(0, x) - \sigma_1 \phi_{d1}(0, x)) \\
&= \delta_1(\phi_{b2}(0, x) - \phi_{b1}(0, x)) - \sigma_1(\phi_{d2}(0, x) - \phi_{d1}(0, x))
\end{aligned}$$

and for sufficiently small $h > 0$,

$$\begin{aligned}
\phi_{d2}(0, x) - \phi_{d1}(0, x) &+ h[f_1(\phi_{d2}, \phi_{b2}, \psi_{d2}, \psi_{b2}) - f_1(\phi_{d1}, \phi_{b1}, \psi_{d1}, \psi_{b1})] \\
&= (1 - h\sigma_1)(\phi_{d2}(0, x) - \phi_{d1}(0, x)) \\
&\quad + h\delta_1(\phi_{b2}(0, x) - \phi_{b1}(0, x)) \\
&\geq 0;
\end{aligned}$$

similarly,

$$\begin{aligned}
\psi_{d2}(0, x) - \psi_{d1}(0, x) &+ h[f_3(\phi_{d2}, \phi_{b2}, \psi_{d2}, \psi_{b2}) - f_3(\phi_{d1}, \phi_{b1}, \psi_{d1}, \psi_{b1})] \\
&= (1 - h\sigma_2)(\psi_{d2}(0, x) - \psi_{d1}(0, x)) \\
&\quad + h\delta_2(\psi_{b2}(0, x) - \psi_{b1}(0, x)) \\
&\geq 0.
\end{aligned}$$

For f_2 ,

$$\begin{aligned}
f_2(\phi_{d2}, \phi_{b2}, \psi_{d2}, \psi_{b2}) &- f_2(\phi_{d1}, \phi_{b1}, \psi_{d1}, \psi_{b1}) \\
&= r_1\phi_{b2}(-\tau_1, x) + \frac{r_1\phi_{b2}^2(0, x)}{\kappa_1} - 2r_1\phi_{b2}(0, x) - \delta_1\phi_{b2}(0, x) \\
&\quad + \sigma_1\phi_{d2}(0, x) - c_1\phi_{b2}(0, x)\psi_{b2}(0, x) + c_1\kappa_1\psi_{b2}(0, x) \\
&\quad - [r_1\phi_{b1}(-\tau_1, x) + \frac{r_1\phi_{b1}^2(0, x)}{\kappa_1} - 2r_1\phi_{b1}(0, x) - \delta_1\phi_{b1}(0, x) \\
&\quad + \sigma_1\phi_{d1}(0, x) - c_1\phi_{b1}(0, x)\psi_{b1}(0, x) + c_1\kappa_1\psi_{b1}(0, x)] \\
&= r_1(\phi_{b2}(-\tau_1, x) - \phi_{b1}(-\tau_1, x)) + \sigma_1(\phi_{d2}(0, x) - \phi_{d1}(0, x)) \\
&\quad + c_1\kappa_1(\psi_{b2}(0, x) - \psi_{b1}(0, x)) + (\phi_{b2}(0, x) - \phi_{b1}(0, x)) \\
&\quad \times [\frac{r_1}{\kappa_1}(\phi_{b2}(0, x) + \phi_{b1}(0, x)) - 2r_1 - \delta_1 - c_1(\psi_{b2}(0, x) \\
&\quad + \psi_{b1}(0, x))] + c_1(\phi_{b2}(0, x)\psi_{b1}(0, x) - \phi_{b1}(0, x)\psi_{b2}(0, x))
\end{aligned}$$

and for sufficiently small $h > 0$,

$$\begin{aligned}
\phi_{b2}(0, x) &- \phi_{b1}(0, x) + h[f_2(\phi_{d2}, \phi_{b2}, \psi_{d2}, \psi_{b2}) - f_2(\phi_{d1}, \phi_{b1}, \psi_{d1}, \psi_{b1})] \\
&= hr_1(\phi_{b2}(-\tau_1, x) - \phi_{b1}(-\tau_1, x)) + h\sigma_1(\phi_{d2}(0, x) - \phi_{d1}(0, x)) \\
&\quad + (\phi_{b2}(0, x) - \phi_{b1}(0, x))\{1 - h[2r_1 + \delta_1 + c_1(\psi_{b2}(0, x) \\
&\quad + \psi_{b1}(0, x)) - \frac{r_1}{\kappa_1}(\phi_{b2}(0, x) + \phi_{b1}(0, x)) - c_1\psi_{b1}]\} \\
&\quad + hc_1(\kappa_1 - \phi_{b1})(\psi_{b2}(0, x) - \psi_{b1}(0, x)) \\
&\geq 0
\end{aligned}$$

since β is the only interior equilibrium of (4.8). And

$$\begin{aligned}
f_4(\phi_{d2}, \phi_{b2}, \psi_{d2}, \psi_{b2}) &- f_4(\phi_{d1}, \phi_{b1}, \psi_{d1}, \psi_{b1}) \\
&= r_2\psi_{b2}(-\tau_2, x) - \frac{r_2\psi_{b2}^2(0, x)}{\kappa_2} - \delta_2\psi_{b2}(0, x) + \sigma_2\psi_{d2}(0, x) \\
&\quad + c_2\phi_{b2}(0, x)\psi_{b2}(0, x) - c_2\kappa_1\psi_{b2}(0, x) \\
&\quad - (r_2\psi_{b1}(-\tau_2, x) - \frac{r_2\psi_{b1}^2(0, x)}{\kappa_2} - \delta_2\psi_{b1}(0, x) + \sigma_2\psi_{d1}(0, x) \\
&\quad + c_2\phi_{b1}(0, x)\psi_{b1}(0, x) - c_2\kappa_1\psi_{b1}(0, x)) \\
&= r_2(\psi_{b2}(-\tau_2, x) - \psi_{b1}(-\tau_2, x)) + \sigma_2(\psi_{d2}(0, x) - \psi_{d1}(0, x)) \\
&\quad + (\psi_{b2}(0, x) - \psi_{b1}(0, x))[c_2\phi_{b2}(0, x) - \frac{r_2}{\kappa_2}(\psi_{b2}(0, x) \\
&\quad + \psi_{b1}(0, x)) - \delta_2 - c_2\kappa_1] + c_2\psi_{b1}(0, x)(\phi_{b2}(0, x) - \phi_{b1}(0, x))
\end{aligned}$$

and for sufficiently small $h > 0$,

$$\begin{aligned}
\psi_{b2}(0, x) & - \psi_{b1}(0, x) + h[f_4(\phi_{d2}, \phi_{b2}, \psi_{d2}, \psi_{b2}) - f_4(\phi_{d1}, \phi_{b1}, \psi_{d1}, \psi_{b1})] \\
& = hr_2(\psi_{b2}(-\tau_2, x) - \psi_{b1}(-\tau_2, x)) + h\sigma_2(\psi_{d2}(0, x) - \psi_{d1}(0, x)) \\
& \quad + (\psi_{b2}(0, x) - \psi_{b1}(0, x))\{1 - h[\frac{r_2}{\kappa_2}(\psi_{b2}(0, x) + \psi_{b1}(0, x)) + \delta_2 \\
& \quad + c_2\kappa_1 - c_2\phi_{b2}(0, x)]\} + hc_2\psi_{b1}(0, x)(\phi_{b2}(0, x) - \phi_{b1}(0, x)) \\
& \geq 0.
\end{aligned}$$

It follows that (4.14) holds. By Corollary 5 in [45], we can show the existence and uniqueness of

$$(u_d(t, x; \phi_d, \phi_b, \psi_d, \psi_b), u_b(t, x; \phi_d, \phi_b, \psi_d, \psi_b), v_d(t, x; \phi_d, \phi_b, \psi_d, \psi_b), v_b(t, x; \phi_d, \phi_b, \psi_d, \psi_b))$$

with

$$\begin{aligned}
(S_1(t, s), S_2(t, s), S_3(t, s), S_4(t, s)) & = (S_1(t - s), S_2(t - s), S_3(t - s), S_4(t - s)), \\
(T_1(t, s), T_2(t, s), T_3(t, s), T_4(t, s)) & = (T_1(t - s), T_2(t - s), T_3(t - s), T_4(t - s)),
\end{aligned}$$

for $t \geq s \geq 0$,

$$\begin{aligned}
& (B_1(t, \phi_d, \phi_b, \psi_d, \psi_b), B_2(t, \phi_d, \phi_b, \psi_d, \psi_b), B_3(t, \phi_d, \phi_b, \psi_d, \psi_b), B_4(t, \phi_d, \phi_b, \psi_d, \psi_b)) \\
& = (f_1(\phi_d, \phi_b, \psi_d, \psi_b), f_2(\phi_d, \phi_b, \psi_d, \psi_b), f_3(\phi_d, \phi_b, \psi_d, \psi_b), f_4(\phi_d, \phi_b, \psi_d, \psi_b)),
\end{aligned}$$

and $v^+ = \beta$, $v^- = \mathbf{0}$. Moreover, by the semigroup theory given in the proof of Theorem 1 in [45], it follows that

$$(u_d(t, x; \phi_d, \phi_b, \psi_d, \psi_b), u_b(t, x; \phi_d, \phi_b, \psi_d, \psi_b), v_d(t, x; \phi_d, \phi_b, \psi_d, \psi_b), v_b(t, x; \phi_d, \phi_b, \psi_d, \psi_b))$$

is a classical solution for $t > \tau$.

Let

$$\Psi(\theta, x) = (\bar{u}_d(t, x), \bar{u}_b(t, x), \bar{v}_d(t, x), \bar{v}_b(t, x))$$

and

$$\Phi(\theta, x) = (\underline{u}_d(t, x), \underline{u}_b(t, x), \underline{v}_d(t, x), \underline{v}_b(t, x)),$$

$\theta \in [-\tau, 0]$, $x \in \mathbb{R}$. Then $\mathbf{0} \leq \Phi \leq \Psi \leq \beta$ with $\Phi \leq \Psi$ in \mathcal{C}_β . Again by Corollary 5 in [45], we have

$$\begin{aligned} \mathbf{0} &\leq (u_d(t, x; \Phi), u_b(t, x; \Phi), v_d(t, x; \Phi), v_b(t, x; \Phi)) \\ &\leq (u_d(t, x; \Psi), u_b(t, x; \Psi), v_d(t, x; \Psi), v_b(t, x; \Psi)) \leq \beta \end{aligned} \quad (4.15)$$

for $t > 0$, $x \in \mathbb{R}$.

Let $v^+ = \beta$ and

$$\begin{aligned} v^- &= (\underline{u}_d(t, x), \underline{u}_b(t, x), \underline{v}_d(t, x), \underline{v}_b(t, x)), \\ v^+ &= (\bar{u}_d(t, x), \bar{u}_b(t, x), \bar{v}_d(t, x), \bar{v}_b(t, x)) \end{aligned}$$

and $v^- = \mathbf{0}$, respectively, we obtain

$$\begin{aligned} &(\underline{u}_d(t, x), \underline{u}_b(t, x), \underline{v}_d(t, x), \underline{v}_b(t, x)) \\ &\leq (u_d(t, x; \Phi), u_b(t, x; \Phi), v_d(t, x; \Phi), v_b(t, x; \Phi)) \\ &\leq \beta \end{aligned} \quad (4.16)$$

for $t \geq 0$ and $x \in \mathbb{R}$, and

$$\begin{aligned} \mathbf{0} &\leq (u_d(t, x; \Psi), u_b(t, x; \Psi), v_d(t, x; \Psi), v_b(t, x; \Psi)) \\ &\leq (\bar{u}_d(t, x), \bar{u}_b(t, x), \bar{v}_d(t, x), \bar{v}_b(t, x)), \end{aligned} \quad (4.17)$$

for $t \geq 0$ and $x \in \mathbb{R}$.

It follows from (4.15)-(4.17) that

$$(\bar{u}_d(t, x), \bar{u}_b(t, x), \bar{v}_d(t, x), \bar{v}_b(t, x)) \geq (\underline{u}_d(t, x), \underline{u}_b(t, x), \underline{v}_d(t, x), \underline{v}_b(t, x))$$

for all $t \geq 0$, $x \in \mathbb{R}$. This completes the proof. \square

Lemma (4.2) together with the global stability results of system (4.8) shows that the time t solution map \mathbf{Q}_t of (4.8) with $t > 0$ exists, and it satisfies Hypotheses 4.1 i-ii since (4.8) is an autonomous system.

LEMMA 4.3. For any $t > 0$, \mathbf{Q}_t satisfies Hypothesis 4.1 iv with β given by (4.3).

Proof. Let $\Phi_1, \Phi_2 \in \mathcal{C}_\beta$. For any $\varepsilon > 0$ and $t_0 > 0$, we define

$$\begin{aligned} H(t, x) &:= |u_d(t, x; \Phi_1) - u_d(t, x; \Phi_2)| + |u_b(t, x; \Phi_1) - u_b(t, x; \Phi_2)| \\ &\quad + |v_d(t, x; \Phi_1) - v_d(t, x; \Phi_2)| + |v_b(t, x; \Phi_1) - v_b(t, x; \Phi_2)|; \\ K &:= \sup_{t \in [0, t_0], x \in \mathbb{R}} H(t, x); \\ \Omega_r(z) &:= [-\tau, 0] \times [z - r, z + r], \quad \forall r > 0, \quad z \in \mathbb{R}; \\ |\Phi|_{\Omega_\rho(z)} &:= \sup_{(\theta, x) \in \Omega_\rho(z)} |\Phi(\theta, x)|; \\ \epsilon_0 &:= \frac{\varepsilon}{2(5+\Delta)t_0 e^{\Delta t_0}}; \end{aligned}$$

where $\Delta := 5r_1 + 3r_2 + 2(\delta_1 + \delta_2 + \sigma_1 + \sigma_2) + (c_1 + c_2)(2\kappa_1 + \kappa_2)$. Without loss of generality, we assume $K \geq \sup_{\theta \in [-\tau, 0], x \in \mathbb{R}} H(\theta, x)$. Then, there exists $(t^*, x^*) \in [0, t_0] \times \mathbb{R}$ such that $H(\theta, x) \leq H(t^*, x^*) + \varepsilon_0$ for $(t, \theta, x) \in [0, t_0] \times [-\tau, 0] \times \mathbb{R}$.

Define

$$\begin{aligned} T_{u_d}(t) &= \frac{1}{\sqrt{4\pi d_{u_d} t}} \int_{-\infty}^{\infty} e^{-\frac{(y-x+e_1 t)^2}{4d_{u_d} t}} dy, & T_{v_d}(t) &= \frac{1}{\sqrt{4\pi d_{v_d} t}} \int_{-\infty}^{\infty} e^{-\frac{(y-x+e_2 t)^2}{4d_{v_d} t}} dy, \\ S_{u_b}(t) &= \frac{1}{\sqrt{4\pi d_{u_b} t}} \int_{-\infty}^{\infty} e^{-\frac{(y-x)^2}{4d_{u_b} t}} dy, & S_{v_b}(t) &= \frac{1}{\sqrt{4\pi d_{v_b} t}} \int_{-\infty}^{\infty} e^{-\frac{(y-x)^2}{4d_{v_b} t}} dy. \end{aligned}$$

Then

$$\begin{aligned} u_d(\xi, t) &= T_{u_d}(t)u_d(0, \cdot)(x) + \int_0^t T_{u_d}(t-s)f_1(u_{ds}, u_{bs}, v_{ds}, v_{bs})(x)ds \\ u_b(\xi, t) &= S_{u_b}(t)u_b(0, \cdot)(x) + \int_0^t S_{u_b}(t-s)f_2(u_{ds}, u_{bs}, v_{ds}, v_{bs})(x)ds \\ v_d(\xi, t) &= T_{v_d}(t)v_d(0, \cdot)(x) + \int_0^t T_{v_d}(t-s)f_3(u_{ds}, u_{bs}, v_{ds}, v_{bs})(x)ds \\ v_b(\xi, t) &= S_{v_b}(t)v_b(0, \cdot)(x) + \int_0^t S_{v_b}(t-s)f_4(u_{ds}, u_{bs}, v_{ds}, v_{bs})(x)ds. \end{aligned}$$

We choose $\sigma = \frac{\varepsilon}{8e^{\Delta t_0}}$ and $M = M(\varepsilon, t_0) > 0$ such that for any $t \in [0, t_0]$

$$\begin{aligned}
\int_{|y|>M} \frac{1}{\sqrt{4\pi d_{u_d} t}} e^{-\frac{(y-x+e_1 t)^2}{4d_{u_d} t}} dy &\leq \frac{\varepsilon_0}{u_d^*}, \\
\int_{|y|>M} \frac{1}{\sqrt{4\pi d_{v_d} t}} e^{-\frac{(y-x+e_2 t)^2}{4d_{v_d} t}} dy &\leq \frac{\varepsilon_0}{v_d^*}, \\
\int_{|y|>M} \frac{1}{\sqrt{4\pi d_{u_b} t}} e^{-\frac{(y-x)^2}{4d_{u_b} t}} dy &\leq \frac{\varepsilon_0}{u_b^*}, \\
\int_{|y|>M} \frac{1}{\sqrt{4\pi d_{v_b} t}} e^{-\frac{(y-x)^2}{4d_{v_b} t}} dy &\leq \frac{\varepsilon_0}{v_b^*}, \\
T_{u_d}(t)H_s(0, x^*) &\leq |H_s|_{\Omega_M(x^*)} + \varepsilon_0, \\
T_{v_d}(t)H_s(0, x^*) &\leq |H_s|_{\Omega_M(x^*)} + \varepsilon_0, \\
S_{u_b}(t)H_s(0, x^*) &\leq |H_s|_{\Omega_M(x^*)} + \varepsilon_0, \\
S_{v_b}(t)H_s(0, x^*) &\leq |H_s|_{\Omega_M(x^*)} + \varepsilon_0, \\
S_{u_b}(t)H_s(-\tau_1, x^*) &\leq |H_s|_{\Omega_M(x^*)} + \varepsilon_0, \\
S_{v_b}(t)H_s(-\tau_1, x^*) &\leq |H_s|_{\Omega_M(x^*)} + \varepsilon_0.
\end{aligned}$$

For $i = 1, 2$ if $|\Phi_1(\theta, x) - \Phi_1(\theta, x)|_{\Omega_M(x^*)} < \sigma$, then

$$\begin{aligned}
& |u_d(t^*, x^*; \Phi_1) - u_d(t^*, x^*; \Phi_2)| \\
&= \left| T_{u_d}(t^*)u_d(0, x^*; \Phi_1) \right. \\
&\quad + \int_0^{t^*} T_{u_d}(t^* - s)f_1(u_{ds}(\cdot, \cdot; \Phi_1), u_{bs}(\cdot, \cdot; \Phi_1), v_{ds}(\cdot, \cdot; \Phi_1), v_{bs}(\cdot, \cdot; \Phi_1))(x^*)ds \\
&\quad - T_{u_d}(t^*)u_d(0, x^*; \Phi_2) \\
&\quad \left. + \int_0^{t^*} T_{u_d}(t^* - s)f_1(u_{ds}(\cdot, \cdot; \Phi_2), u_{bs}(\cdot, \cdot; \Phi_2), v_{ds}(\cdot, \cdot; \Phi_2), v_{bs}(\cdot, \cdot; \Phi_2))(x^*)ds \right| \\
&\leq T_{u_d}(t^*)|u_d(0, x^*; \Phi_1) - u_d(0, x^*; \Phi_2)| \\
&\quad + \int_0^{t^*} T_{u_d}(t^* - s)|f_1(u_{ds}(\cdot, \cdot; \Phi_1), u_{bs}(\cdot, \cdot; \Phi_1), v_{ds}(\cdot, \cdot; \Phi_1), v_{bs}(\cdot, \cdot; \Phi_1)) \\
&\quad - f_1(u_{ds}(\cdot, \cdot; \Phi_2), u_{bs}(\cdot, \cdot; \Phi_2), v_{ds}(\cdot, \cdot; \Phi_2), v_{bs}(\cdot, \cdot; \Phi_2))|(x^*)ds \\
&\leq T_{u_d}(t^*)H(0, x^*) + \delta_1 \int_0^{t^*} T_{u_d}(t^* - s)H_s(0, x^*)ds + \sigma_1 \int_0^{t^*} T_{u_d}(t^* - s)H_s(0, x^*)ds \\
&\leq \sigma + \varepsilon_0 + \delta_1 \int_0^{t_0} (|H_s|_{\Omega_M(x^*)} + \varepsilon_0)ds + \sigma_1 \int_0^{t_0} (|H_s|_{\Omega_M(x^*)} + \varepsilon_0)ds \\
&\leq \sigma + \varepsilon_0(1 + \delta_1 t_0 + \sigma_1 t_0) + (\delta_1 + \sigma_1) \int_0^{t_0} |H_s|_{\Omega_M(x^*)}ds.
\end{aligned}$$

By a similar argument, we have

$$\begin{aligned}
& |v_d(t^*, x^*; \Phi_1) - v_d(t^*, x^*; \Phi_2)| \\
&\leq \sigma + \varepsilon_0(1 + \delta_2 t_0 + \sigma_2 t_0) + (\delta_2 + \sigma_2) \int_0^{t_0} |H_s|_{\Omega_M(x^*)}ds,
\end{aligned}$$

and

$$\begin{aligned}
& |u_b(t^*, x^*; \Phi_1) - u_b(t^*, x^*; \Phi_2)| \\
&= \left| S_{u_b}(t^*)u_b(0, x^*; \Phi_1) \right. \\
&\quad + \int_0^{t^*} S_{u_b}(t^* - s)f_2(u_{ds}(\cdot, \cdot; \Phi_1), u_{bs}(\cdot, \cdot; \Phi_1), v_{ds}(\cdot, \cdot; \Phi_1), v_{bs}(\cdot, \cdot; \Phi_1))(x^*)ds \\
&\quad - S_{u_b}(t^*)u_b(0, x^*; \Phi_2) \\
&\quad \left. + \int_0^{t^*} S_{u_b}(t^* - s)f_2(u_{ds}(\cdot, \cdot; \Phi_2), u_{bs}(\cdot, \cdot; \Phi_2), v_{ds}(\cdot, \cdot; \Phi_2), v_{bs}(\cdot, \cdot; \Phi_2))(x^*)ds \right| \\
&\leq S_{u_b}(t^*)|u_b(0, x^*; \Phi_1) - u_b(0, x^*; \Phi_2)| \\
&\quad + \int_0^{t^*} S_{u_b}(t^* - s)|f_2(u_{ds}(\cdot, \cdot; \Phi_1), u_{bs}(\cdot, \cdot; \Phi_1), v_{ds}(\cdot, \cdot; \Phi_1), v_{bs}(\cdot, \cdot; \Phi_1)) \\
&\quad - f_2(u_{ds}(\cdot, \cdot; \Phi_2), u_{bs}(\cdot, \cdot; \Phi_2), v_{ds}(\cdot, \cdot; \Phi_2), v_{bs}(\cdot, \cdot; \Phi_2))|(x^*)ds \\
&\leq S_{u_b}(t^*)H(0, x^*) + r_1 \int_0^{t^*} S_{u_b}(t^* - s)H_s(-\tau, x)ds \\
&\quad + (4r_1 + \delta_1) \int_0^{t^*} S_{u_b}(t^* - s)H_s(0, x^*)ds \\
&\quad + (\sigma_1 + 2c_1\kappa_1 + c_1\kappa_2) \int_0^{t^*} S_{u_b}(t^* - s)H_s(-\tau, x)ds \\
&\leq \sigma + \varepsilon_0 + r_1 \int_0^{t_0} (|H_s|_{\Omega_M(x^*)} + \varepsilon_0)ds \\
&\quad + (4r_1 + \delta_1 + \sigma_1 + 2c_1\kappa_1 + c_1\kappa_2) \int_0^{t_0} (|H_s|_{\Omega_M(x^*)} + \varepsilon_0)ds \\
&= \sigma + \varepsilon_0[1 + r_1t_0 + (4r_1 + \delta_1 + \sigma_1 + 2c_1\kappa_1 + c_1\kappa_2)t_0] \\
&\quad + (5r_1 + \delta_1 + \sigma_1 + 2c_1\kappa_1 + c_1\kappa_2) \int_0^{t_0} |H_s|_{\Omega_M(x^*)}ds.
\end{aligned}$$

Similarly, we have

$$\begin{aligned}
& |v_b(t^*, x^*; \Phi_1) - v_b(t^*, x^*; \Phi_2)| \\
&\leq \sigma + \varepsilon_0[1 + r_2t_0 + (2r_2 + \delta_2 + \sigma_2 + 2c_2\kappa_1 + c_2\kappa_2)t_0] \\
&\quad + (3r_2 + \delta_2 + \sigma_2 + 2c_2\kappa_1 + c_2\kappa_2) \int_0^{t_0} |H_s|_{\Omega_M(x^*)}ds.
\end{aligned}$$

Thus, we have

$$\begin{aligned}
|H_t|_{\Omega_M(x^*)} &\leq \varepsilon_0 + H(t^*, x^*) \\
&= \varepsilon_0 + |u_d(t^*, x^*; \Phi_1) - u_d(t^*, x^*; \Phi_2)| + |u_b(t^*, x^*; \Phi_1) - u_b(t^*, x^*; \Phi_2)| \\
&\quad + |v_d(t^*, x^*; \Phi_1) - v_d(t^*, x^*; \Phi_2)| + |v_b(t^*, x^*; \Phi_1) - v_b(t^*, x^*; \Phi_2)| \\
&\leq 4\sigma + \varepsilon_0(5 + \Delta)t_0 + \Delta \int_0^{t_0} |H_s|_{\Omega_M(x^*)} ds.
\end{aligned}$$

It follows by Gronwall's inequality that

$$|H_t|_{\Omega_M(x^*)} \leq (4\sigma + \varepsilon_0(5 + \Delta)t_0)e^{\Delta t_0}, \quad \forall t \in [0, t_0].$$

We then obtain that for any small $\varepsilon > 0$, and compact subset $\zeta \subset [-\tau, 0] \times \mathbb{R}$, there exist $\sigma > 0$ and a compact set $\Omega_M(x^*)$ such that $\zeta \subset \Omega_M(x^*)$ and

$$|H_t|_{\zeta} \leq |H_t|_{\Omega_M(x^*)} < \varepsilon \quad \text{for } t \in [0, t_0] \text{ and } |\Phi_1 - \Phi_2|_{\Omega_M(x^*)} < \sigma.$$

This shows that Q_t is continuous in Φ with respect to the compact open topology uniformly for $t \in [0, t_0]$. Note that the metric space (\mathcal{C}_β, d) is complete. By the triangle inequality and the continuity of Q_t in t from Lemma 4.2, it follows that $Q_t(\phi)$ is continuous in $(t; \Phi)$ with respect to the compact open topology. This completes the proof of Lemma 4.3. \square

LEMMA 4.4. *For any $t > 0$, \mathbf{Q}_t satisfies Hypothesis 4.1 v with β given by (4.3).*

We can modify the proof of Lemma 3.3 in [62] by using the specific definition of T_{u_d} , S_{u_b} , T_{v_d} and S_{v_b} in this paper to prove Lemma 4.4. Since the argument is almost the same, we omit the proof.

LEMMA 4.5. *Assume that $\mathbf{w}^{(l)}(c; \theta, x - ct)$ is a nonincreasing traveling wave solution of (4.8) with speed $c \neq 0$ for $i \in \Sigma_0$. Then the family $\mathbf{w}^{(l)}$ is an equicontinuous family of functions.*

Proof. Define

$$(\mathbf{m}_c^{(l)})_i(x) = \frac{\kappa}{d_i^{(l)}(\lambda_{i1}^{(l)} - \lambda_{i2}^{(l)})} \begin{cases} e^{-\lambda_{i1}^{(l)}x} & \text{when } x \geq 0, \\ e^{-\lambda_{i2}^{(l)}x} & \text{when } x < 0, \end{cases}$$

with

$$\begin{aligned} \lambda_{i1}^{(l)} &= \frac{(c-e_i) + \sqrt{(c-e_i)^2 + 4\kappa d_i^{(l)}}}{2d_i^{(l)}} > 0, \\ \lambda_{i2}^{(l)} &= \frac{(c-e_i) - \sqrt{(c-e_i)^2 + 4\kappa d_i^{(l)}}}{2d_i^{(l)}} < 0. \end{aligned}$$

By Theorem 4.1, we have

$$\mathbf{w}^{(l)}(x) = \int_{-\infty}^{\infty} \mathbf{m}_c^{(l)}(x-y) [\mathbf{H}_1(\mathbf{w}^{(l)})(y + c\tau_1) + \mathbf{H}_2(\mathbf{w}^{(l)})(y + c\tau_2) + \mathbf{H}_3(\mathbf{w}^{(l)})(y)] dy. \quad (4.18)$$

Then we can follow the proof of Lemma 4.1 given in [53], therefore we omit the details here. \square

Define $\mathbf{R}_c[\mathbf{u}](\theta, s) = \max\{k\Phi(\theta, s), \mathbf{T}_{-c}[\mathbf{Q}[\mathbf{u}]](\theta, s)\}$ for $\mathbf{u} \in \mathcal{C}_\beta$.

Define a sequence of vector-valued functions $\mathbf{a}_n^{(l)}(c, k; \theta, s)$ of $(\theta, s) \in [-\tau, 0] \times \mathcal{H}$ by the recursion

$$\mathbf{a}_{n+1}^{(l)}(c, k; \theta, s) = \mathbf{R}_{c,k}[\mathbf{a}_n^{(l)}(c, k; \cdot)](\theta, s), \quad \mathbf{a}_0^{(l)}(c, k; \theta, s) = k\Phi(\theta, s). \quad (4.19)$$

and denote $\mathbf{a}^{(l)}$ as the limit of $\mathbf{a}_n^{(l)}(c, k; \theta, s)$ as $n \rightarrow \infty$. Note that $\mathbf{a}_n^{(l)} \leq \mathbf{a}_{n+1}^{(l)} \leq \beta$ for all n , and $\mathbf{a}_n^{(l)}(c, k; \theta, s)$ is nonincreasing in c and s and continuous in $(c, k; \theta, s)$.

Define

$$c^{(l)*} := \sup\{c : \mathbf{a}^{(l)}(c, k; \theta, \infty) = \beta\},$$

and

$$c^{(l)*}_+ := \sup\{c : \mathbf{a}^{(l)}(c, k; \theta, \infty) \neq \mathbf{0}\}.$$

Let

$$\tilde{c}^* = \liminf_{l \rightarrow \infty} c^{(l)*} \quad (4.20)$$

and

$$\tilde{c}_+^* = \liminf_{l \rightarrow \infty} c(l)_+^*. \quad (4.21)$$

THEOREM 4.2. *Assume that Hypotheses 4.1 are satisfied. Then the following statements are true for the system (4.2):*

- i. If $c \geq \tilde{c}^*$ and $c \neq 0$ for $i \in \Sigma_0$, there is a nonincreasing traveling wave solution $\mathbf{w}(x - ct)$ with $\mathbf{w}(c; \theta, -\infty) = \boldsymbol{\beta}$ and $\mathbf{w}(c; \theta, \infty)$ an equilibrium other than $\boldsymbol{\beta}$.*
- ii. If there is a nonincreasing traveling wave $\mathbf{w}(c; \theta, x - ct)$ with $\mathbf{w}(c; \theta, -\infty) = \boldsymbol{\beta}$ and $\mathbf{w}(c; \theta, \infty)$ an equilibrium other than $\boldsymbol{\beta}$, then $c \geq \tilde{c}^*$.*

Proof. As shown in the proof of Theorem 4.2 of Liang and Zhao [67], $\{\mathbf{a}_n^{(l)}(c, k; \theta, s) : n \geq 1, k \in (0, 1]\}$ is a family of equicontinuous functions of (θ, s) in any bounded subset of $[-\tau, 0] \times \mathcal{H}$. Since $\mathbf{a}_n^{(l)}$ is nondecreasing in n , the whole sequence $\mathbf{a}_n^{(l)}(c, k; \theta, s)$ converges to a function $\mathbf{a}^{(l)}(c, k; \theta, s)$ uniformly for $\theta \in [-\tau, 0]$ and s on bounded sets. In particular, $\mathbf{a}^{(l)}(c, k; \theta, s)$ is a continuous function of (θ, s) . By hypothesis 4.1 iv, we take limits of (4.19) and we have

$$\mathbf{a}^{(l)}(c, k; \theta, s) = \max\{k\Phi(\theta, s), \mathbf{Q}[\mathbf{a}^{(l)}(c, k; \cdot)](\theta, s + c)\}. \quad (4.22)$$

Fix $\theta_0 \in [-\tau, 0]$. For any integer g we define

$$\mathbf{K}_k(g) := \frac{1}{2}[\mathbf{a}^{(l)}(c, k; \theta_0, g) + \mathbf{a}^{(l)}(c, k; \theta_0, g + 1)]. \quad (4.23)$$

Note that $\mathbf{K}_k(g)$ is nonincreasing in g . Since $\mathbf{K}_k(-\infty) = \boldsymbol{\beta}(\theta_0)$ and $\mathbf{K}_k(\infty) = \mathbf{0}$, there exists g_k such that

$$\frac{N-2}{N} |\boldsymbol{\beta}(\theta_0)| \leq \mathbf{K}_k(g_k) \leq \frac{N-1}{N} |\boldsymbol{\beta}(\theta_0)|, \quad (4.24)$$

for some large positive integer N .

Now consider $\mathbf{a}^{(l)}(c, k; \theta, s + g_k)$.

Claim: $\mathbf{a}^{(l)}(c, k; \theta, s)$ forms a family of equicontinuous function of (θ, s) in any bounded subsets of $[-\tau, 0] \times \mathcal{H}$.

For any $\theta_1, \theta_2 \in [-\tau, 0]$ and real numbers s_1 and s_2 , we have that for any positive integer n ,

$$\begin{aligned} |\mathbf{a}^{(l)}(c, k; \theta_1, s_1) - \mathbf{a}^{(l)}(c, k; \theta_2, s_2)| &\leq |\mathbf{a}^{(l)}(c, k; \theta_1, s_1) - \mathbf{a}_n^{(l)}(c, k; \theta_1, s_1)| \\ &\quad + |\mathbf{a}^{(l)}(c, k; \theta_2, s_2) - \mathbf{a}_n^{(l)}(c, k; \theta_2, s_2)| \\ &\quad + |\mathbf{a}_n^{(l)}(c, k; \theta_1, s_1) - \mathbf{a}_n^{(l)}(c, k; \theta_2, s_2)|. \end{aligned}$$

Since $\mathbf{a}_n^{(l)}$ increases to $\mathbf{a}^{(l)}$ uniformly on bounded sets and $\{\mathbf{a}_n^{(l)}(c, k; \theta, s) : n \geq 1, k \in (0, 1]\}$ is a family of equicontinuous functions of (θ, s) , one can show that the above claim is true.

Thus we can find a sequence $k_i \rightarrow 0$ such that $\mathbf{a}^{(l)}(c, k_i; \theta, s + g_{k_i})$ converges uniformly for $\theta \in [-\tau, 0]$ and s on bounded sets to a function $\mathbf{w}^{(l)}(c; \theta, s)$ that is nonincreasing in s .

Taking limits in (4.22) with $k = k_i$ and $s = s + g_{k_i} - c$ and using the translation invariance of \mathbf{Q} , we find that

$$\mathbf{w}^{(l)}(c; \theta, s - c) = \mathbf{Q}[\mathbf{w}^{(l)}(c; \cdot)](\theta, s). \quad (4.25)$$

So $\mathbf{u}_n(\theta, s) = \mathbf{w}^{(l)}(c; \theta, s - nc)$ is a traveling wave solution of the recursion $\mathbf{u}_{n+1} = \mathbf{Q}[\mathbf{u}_n]$, $n = 0, 1, 2, \dots$

Let s approach to $-\infty$ in (4.25), then

$$\mathbf{w}^{(l)}(c; \cdot, -\infty) = \lim_{n \rightarrow \infty} \mathbf{w}^{(l)}(c; \cdot, s - (n+1)c) = \lim_{n \rightarrow \infty} \mathbf{Q}^n[\mathbf{w}^{(l)}](\cdot, s) = \mathbf{Q}[\mathbf{w}^{(l)}(c; \cdot, -\infty)]$$

for $\forall s \in \mathcal{H}$, and subsequently we consider s approach to $-\infty$, we have

$$\mathbf{w}^{(l)}(c; \cdot, \infty) = \lim_{s \rightarrow \infty} \mathbf{w}^{(l)}(c; \cdot, s - c) = \lim_{s \rightarrow \infty} \mathbf{Q}[\mathbf{w}^{(l)}](\cdot, s) = \mathbf{Q}[\mathbf{w}^{(l)}(c; \cdot, \infty)],$$

for $\forall s \in \mathcal{H}$. It follows that $\mathbf{w}^{(l)}(c; \cdot, \pm\infty)$ are equilibria of \mathbf{Q} .

The definition (4.23) shows that as $k_i \rightarrow 0$ the sequence $\mathbf{K}_{k_i}(g_{k_i})$ converges to $\frac{1}{2}[\mathbf{w}^{(l)}(c; \theta_0, 0) + \mathbf{w}^{(l)}(c; \theta_0, 1)]$. Since $\mathbf{w}^{(l)}(c; \theta, s)$ is nonincreasing in s ,

$$\frac{N-2}{N} |\boldsymbol{\beta}(\theta_0)| \leq \lim_{k_i \rightarrow 0} \mathbf{K}_{k_i}(g_{k_i}) \leq \mathbf{w}^{(l)}(c; \theta_0, -\infty)$$

and

$$\mathbf{w}^{(l)}(c; \theta_0, \infty) \leq \lim_{k_i \rightarrow 0} \mathbf{K}_{k_i}(g_{k_i}) \leq \frac{N-1}{N} |\boldsymbol{\beta}(\theta_0)|.$$

Thus, we have $\mathbf{w}^{(l)}(c; \theta_0, \infty) \neq \boldsymbol{\beta}$ and $\mathbf{w}^{(l)}(c; \theta_0, -\infty) = \boldsymbol{\beta}$ due to the choice of N . We have proved that (4.8) has a nonincreasing traveling wave solution $\mathbf{w}^{(l)}(c; \theta, s - nc)$ with $\mathbf{w}^{(l)}(c; \theta_0, -\infty) = \boldsymbol{\beta}$ and $\mathbf{w}^{(l)}(c; \theta_0, \infty)$, an equilibrium other than $\boldsymbol{\beta}$.

Since $\boldsymbol{\beta}$ is the only interior equilibrium of $\mathcal{C}_{\boldsymbol{\beta}}$, we can choose $\eta > 0$ small enough such that there is no constant equilibrium other than $\boldsymbol{\beta}$ in the set $\{\mathbf{w} \in \mathcal{C}_{\boldsymbol{\beta}} : |\boldsymbol{\beta} - \mathbf{w}| \leq \eta\}$. By the Intermediate Value Theorem, it shows that there exists a real number s^* at which $|\boldsymbol{\beta} - \mathbf{w}^{(l)}(\theta_0, s^*)| = \eta$, since as s increases from $-\infty$ to ∞ , the continuous function $|\boldsymbol{\beta} - \mathbf{w}^{(l)}(\theta_0, s)|$ increases from 0 to a positive real number. We can assume $s^* = 0$ by translating if necessary, and we have

$$|\boldsymbol{\beta} - \mathbf{w}^{(l)}(\theta_0, 0)| = \eta.$$

By Lemma 4.5, $\mathbf{w}^{(l)}$ is an equicontinuous family of functions. Then using Ascoli's Theorem, we have that $\mathbf{w}^{(l)}(x)$ has a subsequence $\{\mathbf{w}^{(l_j)}(x)\}$ such that $\{\mathbf{w}^{(l_j)}(x)\}$ converges to $\mathbf{w}(x)$ uniformly on every bounded interval. Clearly,

$$|\boldsymbol{\beta} - \mathbf{w}(\theta_0, 0)| = \eta. \tag{4.26}$$

One can show that

$$\lim_{l \rightarrow \infty} \int_{-\infty}^{\infty} |\mathbf{m}_c^{(l)}(x) - \mathbf{m}_c(x)| dx = \mathbf{0}, \tag{4.27}$$

where $(\mathbf{m}_c^{(l)})_i(x)$ is defined in the proof of Lemma 4.5. The proof can be found in Li [53].

Observe that $\mathbf{w}^{(l_j)}$ satisfies

$$\begin{aligned}
\mathbf{w}^{(l_j)}(x) &= \int_{-\infty}^{\infty} \mathbf{m}_c^{(l_j)}(x-y) [\mathbf{H}_1(\mathbf{w}^{(l_j)})(y+c\tau_1) \\
&\quad + \mathbf{H}_2(\mathbf{w}^{(l_j)})(y+c\tau_2) + \mathbf{H}_3(\mathbf{w}^{(l_j)})(y)] dy \\
&= \int_{-\infty}^{\infty} \mathbf{m}_c(x-y) [\mathbf{H}_1(\mathbf{w}^{(l_j)})(y+c\tau_1) \\
&\quad + \mathbf{H}_2(\mathbf{w}^{(l_j)})(y+c\tau_2) + \mathbf{H}_3(\mathbf{w}^{(l_j)})(y)] dy \\
&\quad + \int_{-\infty}^{\infty} [\mathbf{m}_c^{(l_j)}(x-y) - \mathbf{m}_c(x-y)] [\mathbf{H}_1(\mathbf{w}^{(l_j)})(y+c\tau_1) \\
&\quad + \mathbf{H}_2(\mathbf{w}^{(l_j)})(y+c\tau_2) + \mathbf{H}_3(\mathbf{w}^{(l_j)})(y)] dy.
\end{aligned} \tag{4.28}$$

Taking limits of (4.28), we obtain

$$\mathbf{w}(x) = \int_{-\infty}^{\infty} \mathbf{m}_c(x-y) [\mathbf{H}_1(\mathbf{w})(y+c\tau_1) + \mathbf{H}_2(\mathbf{w})(y+c\tau_2) + \mathbf{H}_3(\mathbf{w})(y)] dy.$$

By Theorem 4.1, $\mathbf{w}(x)$ is a traveling wave solution of (4.2) with speed \tilde{c}^* . The condition (4.26) and the definition of η indicate that $\mathbf{w}(-\infty) = \boldsymbol{\beta}$ and $\mathbf{w}(\infty)$ is a constant equilibrium of (4.2) other than $\boldsymbol{\beta}$. This completes the proof of the statement (i) of the theorem.

The proof of the statement (ii) is similar to the second part of the proof of Theorem 3.1 in Li and Weinberger [61], we omit it here. So the proof of the theorem is completed. \square

REMARK 4.3. *Assume that Hypotheses 4.1 are satisfied. Then the following statements are true for the system (4.2):*

- i. *if $c \geq \tilde{c}_+^*$ and $c \neq 0$ for $i \in \Sigma_0$, there is a nonincreasing traveling wave solution $\mathbf{w}(x-ct)$ with $\mathbf{w}(c; \theta, \infty) = \mathbf{0}$ and $\mathbf{w}(c; \theta, -\infty)$ an equilibrium other than $\mathbf{0}$; and*
- ii. *if there is a nonincreasing traveling wave $\mathbf{w}(c; \theta, x-ct)$ with $\mathbf{w}(c; \theta, \infty) = \mathbf{0}$ and $\mathbf{w}(c; \theta, -\infty) = \boldsymbol{\beta}$, then $c \geq \tilde{c}_+^*$.*

The proof is similar to that of Theorem 4.2 and can be found in [53].

In this chapter, we first constructed the integral system by defining $\mathbf{H}_1(\mathbf{u})$, $\mathbf{H}_2(\mathbf{u})$, $\mathbf{H}_3(\mathbf{u})$ and $\mathbf{m}_c(x)$. Then we showed that a traveling wave solution of the cooperative system (4.2) with a proper speed is a fixed point of a compact integral operator. Finally we took the limit of a sequence of functions that are fixed points of the related integral system, and Theorem 4.2 and Remark 4.3 showed that the existence of traveling wave solutions can be established with speeds above two extended real numbers, \tilde{c}^* and \tilde{c}_+^* .

CHAPTER 5

CONCLUSION AND FUTURE DIRECTIONS

5.1 Conclusion

In this dissertation we formulated a system of delayed reaction-diffusion equations which modeled growth, spread and competition of two species with stage structure. This model is an extension of the time-delayed population system with stage structure by Zhang et al. [64]. However, there is no compartmentalization for both species in their model. The advantage of our model is that we take all factors of compartmentalization, stage structure and interaction between two species into consideration in order to provide a resolution to the drift paradox in stream ecology. To the best of our knowledge, this is the first model involving all these factors. The underlying dynamics are very complicated, however we can still give a complete description of the global stability and traveling wave solutions.

In Chapter 3 we analyzed the non-spatial system (3.1) in which the effect of spatial advection and diffusion is not involved. We obtained the existence and local stability criteria of the equilibria of the non-spatial system (3.1). Then using the fluctuation lemma and constructing sequences approaching equilibrium points we showed that the global stability of the equilibria in our model can be completely determined. The mathematical methods used in our proofs are inspired by Al-Omari and Gourley's work [63]. By the study of the non-spatial system (3.1), we conclude that (i) the two interactive species with stage structure can persist

in a stream; (ii) one species out-competes the other one, and the species cannot coexist; (iii) the two species can coexist and approach a stable population density in long term under certain conditions (i.e. the two mono-culture equilibria E_1 and E_2 are both unstable).

The spatial system (4.1) is analyzed in Chapter 4. We defined the integral system and showed that a traveling wave solution of a delayed cooperative reaction-diffusion system with a proper speed is a fixed point of a compact integral operator. Further, we established the existence of traveling wave solutions with speeds above two extended real numbers by taking a limit of a sequence of functions that are fixed points of related integral systems. In biology, traveling waves are spatial transitions from an unstable state to a stable one. In other words, the existence of traveling wave solutions connecting two equilibria means that the unstable equilibrium is took over by the stable one in space as time increases.

5.2 Discussion

In Chapter 4 we proved the existence of traveling wave solutions with speeds above two extended real numbers \tilde{c}^* and \tilde{c}_+^* . We are interested in how \tilde{c}^* is related to c^* and how \tilde{c}_+^* is related to c_+^* . We want to find conditions, under which the linear determinacy conditions given in Weinberger et al. [52] are satisfied by (4.2), such that $\tilde{c}^* = \tilde{c}_+^* = c^* = c_+^*$ and they are all equal to the unique spreading speed of (4.2).

Li in [53] showed that $\tilde{c}^* = \tilde{c}_+^* = c^* = c_+^* = \bar{c}$ for the general partially degenerate cooperative reaction-diffusion system

$$\frac{\partial \mathbf{u}}{\partial t} = D \frac{\partial^2 \mathbf{u}}{\partial x^2} - E \frac{\partial \mathbf{u}}{\partial x} + \mathbf{f}(\mathbf{u}(t, x)), \quad (5.1)$$

where

$$\bar{c} := \inf_{\mu > 0} (1/\mu) \gamma_1(\mu) \quad (5.2)$$

and $\gamma_1(\mu)$ is the principal eigenvalue of the first irreducible diagonal block of the moment generating matrix C_μ of the linearized system of (5.1). He showed that \bar{c} can be characterized as the slowest speed of a class of traveling wave solutions by verifying the linear determinacy conditions under appropriate assumptions.

However, in our system (4.4) the time delay is considered in the vector function $\mathbf{f}(\mathbf{u}(\theta, \mathbf{t}, \mathbf{x}))$. Consequently the principal eigenvalue $\gamma_1(\mu)$ of C_μ and the corresponding eigenvector $\boldsymbol{\xi}(\mu)$ cannot be expressed explicitly. Thus the ideas used in [53] cannot be applied in our system.

In order to verify the linear determinacy conditions, one might first write the eigenvector $\boldsymbol{\xi}(\mu)$ as a function of the principal eigenvalue $\gamma_1(\mu)$. Then using the fact that the wave speed equation $\phi(\mu) = (1/\mu)\gamma_1(\mu)$ is a convex function and thus the infimum in Eq. (5.2) exists, one might provide an estimation of $\gamma_1(\mu)$ and therefore show that the linear determinacy conditions are satisfied under appropriate assumptions.

Liang and Zhao [67] developed the analytical theory on the spreading speeds for delayed cooperative systems, which can be applied on our cooperative model (4.2).

5.3 Future Directions

This model can be extended in several different directions:

1. **Consider species interaction in the streamflow.** In stream ecology, many studies have been done to study how different organisms interact with each other and to understand the interconnections and impacts [21, 70, 71]. Different interactions include competition among individuals of the same species, competition and predation between different species. We may add terms for the populations in the drift to indicate their interaction, and these

terms can even be nonlinear (density-dependent). By analyzing the new model, one may predict the dynamics of species in the flow such as how the numbers of each species are influenced by its prey, its competitors, its predators, and even diseases.

2. **Add age structure for adult individuals.** New age structure among adult members can be considered in the model, i.e. dividing each adult population into two groups regarding their productivity, young adults and old adults. Only young and healthy adult members have strong productivity, and the old and unhealthy ones do not contribute to reproduction. One can define n_i , n_{my} and n_{mo} to represent the population density of immature members, young mature members and old members, respectively. Notice that these three variables interact with each other.
3. **Density-dependent diffusion rate.** If organisms are either attracted to each other or repelled from one another, then we may replace the simple diffusion term by a biased random motion model [72]. In reality, organisms tend to join together at low densities and to estrange one another at high densities. Such a density-dependent response can be modeled by a function $\psi(u)$ of population density [73], where $\psi(u)$ is negative at low densities and positive at high densities and u is the population density.
4. **Consider an Allee effect.** Allee effect is the positive relationship between population density and individual fitness [77]. In other words, at low density the population does not grow optimally. Since many species experience an Allee effect, we may add an Allee effect in the growth function of species. Wang et al. [74] claimed that systems with Allee effect show destabilization compared to a LotkaVolterra-type competitive system. However, they only conducted phase plane analysis and numerical simulation, and the time delay

was not considered.

5. **Consider stochastic fluctuations in population growth.** Population dynamics is also determined by the environmental stochasticity, which includes climate effects, effects of human interaction and effects of food resources. For example, in the summer a population may grow favorably because of an abundant food supply and the agreeable climate, while in the winter they may experience a large number of deaths and low reproduction rate due to drought or low temperature. Our present model assumes that the environment is temporally constant, and we may use a stochastic variable representing the growth function to model these random effects [75, 76].

CURRICULUM VITAE

CHUNWEI WANG

EDUCATION

University of Louisville, Louisville, KY
Ph.D., Applied and Industrial Mathematics, Summer 2013
M.A., Applied and Industrial Mathematics, August 2011
Beijing University of Technology, Beijing, China
B.S., Information and Computing Sciences, July 2005

PROFESSIONAL EXPERIENCE

Graduate Teaching Assistant, University of Louisville, Louisville, KY
Math 111: College Algebra, Recitation Instructor Aug. 2008 - May 2013
Math 105: Introduction to Contemporary Mathematics
Math 107: Finite Mathematics
Math 109: Elementary Statistics
Math 180: Elements of Calculus
Math 111, 105, 107, 180, Lecture Instructor Summer 2009 - Summer 2012

Research Experience May 2009 - May 2013
University of Louisville, Louisville, KY

Private Tutor and University of Louisville Math Lab Tutor
Louisville, KY Aug. 2008 - Apr. 2013

Test Engineer Jul. 2005 - Jul. 2007
Beyondsoft Corporation, Beijing, China

TALKS & PRESENTATIONS

Introduction to Delay Differential Equations. May 2010
Math Biology Seminar, University of Louisville, Louisville, KY

**Optimization of The Temporary Commercial Network
For The 2008 Beijing Olympics.** Jul. 2005
Applied Math Seminar, Beijing University of Technology, Beijing, China

AWARDS

Ken F. and Sandra S. Hohman Fellowship,
University of Louisville, Louisville, KY

Aug. 2008 - May 2009

Second Place Scholarship,
Beijing University of Technology, Beijing, China

Aug. 2001 - Aug. 2004

PROFESSIONAL MEMBERSHIPS

American Mathematical Society

Since 2008

Tri-State Actuarial Club

Since 2012
