by the following dissertation committee

Dr. Bradley A. Campbell

Dr. Gennaro F. Vito

Dr. Benjamin W. Fisher

Dr. Eryn N. O'Neal

DEDICATION

I am grateful to my family and friends who helped me throughout my academic career, and cannot thank them enough. That said, I would like to dedicate my dissertation and acknowledge some of the many people who helped me during this long journey. First, I want to dedicate this dissertation to my wife, Taylor Lapsey, who has given me endless love and support. She has been my primary motivation throughout this process, and I am very lucky to have married such a wonder person. Next, I would like to acknowledge others who have given me great support and guidance. Specifically, my dad, David Lapsey Sr, who instilled in me hard work and a drive for success at a early age, and inspired me to continue my education and never quit. Additionally, my family members, including my brothers, mom, and in-laws gave me the inspiration and support needed to complete this project. I would also like to thank my friends for always being there during the eleven years required to complete this degree, and making sure I had plenty of fun during the process. You guys know who you are. I would like to give a big shoutout to the professors at UofL and my committee members for teaching me everthing I know and helping make this happen. I am especially thank Dr. Bradley Campbell, who I have worked with since I was a Master's, and who always offers me guidance and advice. I greatly appreciate the time he spent coaching me these years, and will always be grateful for the opportunities he has provided, and helping make this happen. Finally, I would like to thank my cohort and officemates. I am lucky to have shared my experiences with such excellent people.

ABSTRACT

FOCAL CONCERNS AND CASE ADVANCEMENT IN SEXUAL ASSAULT CASES: A SYSTEMATIC REVIEW AND META-ANALYSIS

David Stuart Lapsey Jr

April 23rd, 2021

Scholars have frequently used focal concerns to explain case advancement – *suspect identification, case clearance, and arrest and charge decisions* – in sexual assault cases. Indeed, focal concerns has been popularly used to explain prosecutor decision-making and, more recently, it has increasingly been used to explain police decision-making in sexual assault cases. As such, a systematic review and meta-analysis is needed to synthesize and evaluate existing literature. In this study, meta-analysis is used to estimate the overall size, strength, and direction of focal concerns variables on case advancement in sexual assault cases by using police officers’ decision to arrest and prosecutors’ decision to charge. This evaluation will follow protocols recommended by the Campbell Collaboration of Systematic Reviews to conduct an exhaustive literature search and use meta-analytic techniques to estimate effect sizes. Results from this study will hopefully help inform policy and training by determining factors associated sexual assault case advancement.

CHAPTER 1

INTRODUCTION

Historically, sexual assault victims have been treated poorly by criminal justice practitioners (Brownmiller, 1975; R. Campbell et al., 2001; Frohman, 1991), and sexual assault cases suffer from high levels of case attrition (Frazier & Haney, 1996; Gregory & Lees, 1996). For instance, Morabito and colleagues (2019b) found that only 17.5% of sexual assault reports resulted in arrest, 72% of arrests resulted in charges filed, and 12.5% of total reports resulted in a conviction. Indeed, survivors are often met with skepticism and maltreatment when reporting victimization and throughout the criminal justice process (Estrich, 1987; Frohman, 1991; Maier, 2008). These harms experienced by survivors during the criminal justice process have been termed “secondary victimization” (R. Campbell et al., 2001; Maier, 2008), which has shown to reduce victim engagement with police and prosecutors (R. Campbell, 2008; Frohman, 1991), and can increase long-term post-assault trauma experienced by survivors (Campbell et al., 2001). Additionally, negative perceptions of victims can prevent practitioners from advancing a case and pursuing criminal charges (Galton, 1975; Kelley & Campbell, 2013; Martin & Powell, 1994). Finally, when victims are treated poorly by practitioners, it can contribute to the onset of long-term consequences for victims including post-traumatic stress disorder (PTSD), elevated rates of substance abuse, and greater risk of future victimization (R. Campbell, 2012; Marx et al., 2008; Ullman & Filipas, 2011).

One contributor to this secondary victimization is police officers' and prosecutors' adherence to rape myths, or stereotypes and misconceptions regarding what practitioners perceive as a "real rape" (Brownmiller, 1975; Estrich, 1987; Lonsway, 2010). Estrich (1987) described practitioners' perception of "real rape" as an offense that included an offender using force during the assault, a victim sustaining injuries, and assaults committed by strangers. If characteristics fail to meet police or prosecutors' expectation of "real rape", then practitioners may blame the victim, question their credibility and the veracity of the allegations, and subsequently the odds of case advancement are diminished (Bouffard, 2000; Campbell, 2008; Estrich, 1987; Jordan, 2004; Lafree, 1981).

For decades, practitioners and advocates have called for improved responses to sexual assault cases (Feilds, 1978), which has moved scholars to conduct studies aimed at identifying correlates of decision-making (Bouffard, 2000; Kestetter, 1990; Kingsworth et al., 1999; Lafree, 1981). Research on this topic has focused primarily on case characteristics (e.g., physical evidence, availability of witnesses, victim injury, suspect weapon use), victim characteristics (e.g., victim-offender relationship, victim race, victim resistance, prompt report of victimization to police), and officers' judgements about victim credibility to determine which characteristics affect case advancement and attrition (Alderden & Ullman, 2012b; Beichner & Spohn, 2005; Beichner & Spohn, 2012; B. Campbell et al., 2015; Kaiser et al., 2017; Morabito et al., 2019a; O'Neal et al., 2019; Scott & Beaman, 2004; Spohn et al., 2001; Spohn & Tellis, 2019;).

Findings from this line of research have produced mixed results for both police and prosecutors and report similar factors that impact decision-making. Indeed, studies

have found physical evidence (Beichner & Spohn, 2005; Kaiser et al., 2017; Morabito et al., 2019b; Spohn & Holleran, 2001), witness(es) to the assault (eg., fresh complaint and eye witnesses) (Beichner & Spohn, 2005; Kaiser et al., 2017; Kingsnorth et al., 1999; Morabito et al., 2019b; Spohn & Tellis, 2019; O'Neal et al., 2019), victim injury (Frazier & Haney, 1996; Kerstetter, 1990; Kingsnorth et al., 1999; Morabito et al., 2019b; Spohn & Tellis, 2019; Venema et al., 2019; Wentz & Keimig, 2019), and suspect weapon use (Kerstetter, 1990; LaFree, 1981; Morabito et al., 2019b; Spohn et al., 2001; Spohn & Tellis, 2019; Venema et al., 2019) were significantly correlated with higher likelihood of case advancement. However, some have found physical evidence (O'Neal et al., 2019; Spears & Spohn, 1997; Spohn et al., 2001), witness(es) to the assault (Alderden & Ullman, 2012a; Spears & Spohn, 1997; Wentz, 2019), victim injury (Alderden & Ullman, 2012; Scott & Beaman, 2004; Wood et al., 2011), and suspect weapon use (Frazier & Haney, 1996; Kaiser et al., 2017; Scott & Beaman, 2004; Ylang & Holtfreter, 2019) were not significantly correlated with case advancement.

Regarding victim characteristics, studies have found intimate partner relationships (Alderden & Ullman, 2012b; Kaiser et al., 2017; Morabito et al., 2019b; Spohn et al., 2001), non-stranger relationships (Alderden & Ullman, 2012b; Morabito et al., 2019b), victim race (e.g. Black, Hispanic, White), (Morabito et al., 2019b; Spohn & Horney, 1993; Spohn & Spears, 1996; Venema et al., 2019), victims who physically and/or verbally resisted their assailant (Alderden & Ullman, 2012ab; Kerstetter, 1990; Morabito et al., 2019; Spohn & Spears, 1996), and prompt reporting of victimization to police (Beichner & Spohn, 2005; Kaiser et al., 2017; LaFree, 1981; Morabito et al., 2019b; Spohn & Tellis, 2019; O'Neal et al., 2019) were significantly correlated with increased

odds of case advancement. Yet, others did not detect a significant relationship between intimate partner relationships (O’Neal et al., 2019; Spohn & Tellis, 2019), non-stranger relationships (Beichner & Spohn, 2005; Kaiser et al., 2017; O’Neal et al., 2019; Spohn & Tellis, 2019), victim resistance (Kaiser et al., 2017; Scott & Beaman, 2004; Spears & Spohn, 1997; Spohn et al., 2001; Spohn & Holleran, 2001; Spohn & Tellis, 2019; O’Neal et al., 2019), prompt victim report of victimization to police (Holleran et al., 2010; Tasca et al., 2013; Spears & Spohn, 1997; Spohn & Holleran, 2001), and victim race (Bouffard, 2000; Frazier & Haney, 1996; Kaiser et al., 2017; Spears & Spohn, 1997; Spohn & Tellis, 2019) with case advancement.

In addition, scholars have studied practitioner perceptions of victim credibility, an extralegal variable that are variables practitioners should not consider legally relevant rather legal variables that should be legal factors considered in decision-making. Extralegal variables include variables prosecutors and police associated with misconceptions about victims that are not supposed to be considered when making decisions about case outcomes (i.e., actions and behaviors displayed before, during, and after victimization) (B. Campbell et al., 2015; Frohman, 1991), and report mixed findings regarding its impact on practitioner decision-making. For instance, some found when practitioners questioned a victim’s credibility (e.g., victim alcohol use prior or during the assault, questions about victim character/reputation, risk taking behavior) the odds of case advancement significantly decreased (Alderden & Ullman, 2012b; Beichner & Spohn, 2005, 2012; Kaiser et al., 2017; Morabito et al., 2019a; Spears & Spohn, 1997). Additionally, some found when practitioners questioned a victim’s credibility odds of case advancement significantly decreased (Alderden & Ullman, 2012a), and others found

an nonsignificant correlation between victim credibility and case advancement (Holleran et al., 2010; Morabito et al., 2019a; O’Neal et al., 2019; Spohn & Tellis, 2019).

To explain correlates of practitioner decision-making at multiple stages scholars have relied on the focal concerns perspective (Hartley et al., 2007). Originally developed to explain judicial decisions and sentencing disparities, focal concerns suggests that judges make decisions based on three concepts: (a) the blameworthiness of the offender, (b) the perceived dangerousness of the offender or the need to protect the community, and (c) practical and resources constraints faced by the criminal justice system (Steffensmeier et al., 1998). Additionally, Steffensmeier and colleagues (1998) suggested judges are forced to make decisions with limited time and resources, as well as limited knowledge about an offender’s prior criminal history. Thus, judges rely on a “perceptual shorthand” based on extra-legal variables (e.g., offender race, age, gender) to determine their responsibility for the offense and future dangerousness posed by the offender (Steffensmeier et al., 1998). Similar to judges, scholars have found police and prosecutors make decisions based on their perceived likelihood of case advancement. For instance, police make decisions based on whether they believe a prosecutor will accept charges, whereas prosecutors assess a case’s “convictability” (e.g., likelihood of conviction) and whether they believe a jury would find the offender guilty at trial (B. Campbell, 2015; Spohn et al., 2014; Tillyer & Hartley., 2010). If police believe a prosecutor will decline charges or prosecutors believe a juror will find the offender not guilty, then case advancement is unlikely.

The focal concerns framework has been used explain prosecutor decisions in sexual assault cases for dating back to 2001 (Beichner & Spohn, 2005, 2012; O’Neal &

Spohn, 2017; Spohn et al., 2001) and more recently to explain police decision-making (O'Neal & Spohn, 2017; Spohn & Tellis, 2019). To explain decision-making in sexual assault cases scholars have used common correlates associated with focal concerns variables (Kaiser et al., 2017; Spohn & Tellis, 2019; Venema et al., 2019; Wentz 2019, Ylang & Holtfreter, 2019). Specifically, scholars have used focal concerns to explain sexual assault investigative outcomes and understand how *suspect blameworthiness* (e.g., victim injury, victim resistance), *protection of the community* (e.g., suspect used weapon), *practical constraints* (e.g., physical evidence, witness(es), and *perceptual shorthand* (e.g., victim-offender relationship, victim credibility) influence practitioner decisions (O'Neal & Spohn, 2017; Spohn & Tellis, 2019).

Although many studies use common correlates that measure focal concerns, O'Neal and Spohn (2017) were the first to formally operationalize and measure focal concerns concepts in sexual assault cases. First, they defined offender blameworthiness as offense specific harm to the victim and/or practitioner perception of whether the victim resisted their attacker. Second, protection of the community represents the severity of the assault or the heinousness of the offender's actions. It follows that, if a suspect used a weapon, then the case would be perceived as more heinous and necessitate a greater need to protect the community. Third, practical constraints are factors beyond the control of police and prosecutors, which include physical evidence left during a crime or witnesses corroborating the assault. Fourth, perceptual shorthand are generally extralegal variables practitioners should disregard, often include misconceptions about rape and rape victims, and usually fit with rape myth acceptance. O'Neal and Spohn (2017) provided more standardized measurement of focal concerns to promote consistency across studies and

thus a path to improve study replication, generalizability, effect size estimate precision, and understanding the relationships between focal concerns and case advancement in sexual assault cases. Though most studies have not specifically operationalized variables into focal concerns concepts, many studies have used measures that tap into O'Neal and Spohn's definitions to explain practitioner decision-making in sex crimes cases (see Kaiser et al., 2015; Spohn & Tellis, 2019; Venema et al., 2019; Wentz, 2019; Ylang & Holtfreter, 2019). However, no systematic review has been conducted to evaluate the applicability of the focal concerns perspective to explain case advancement, and there has been no systematic review to determine which characteristics are most important to case advancement.

The literature previously discussed provides an overview on how case characteristics, victim characteristics, and victim credibility influence practitioner decision-making in sexual assault cases. Because of the mixed results detected across studies regarding police and prosecutor decision-making in sexual assault cases, a systematic review and meta-analysis are needed to understand which focal concerns are most important to practitioner decision-making (Cullen, 2005) and how applicable focal concerns is to police and prosecutor decision-making in sexual assault cases. As a result, I aim to differentiate the most important correlates of arrest and charging to inform evidence-based policy. The findings will be useful to inform training for police and prosecutors about rape myths and misconceptions, evidence processing, maintaining victim engagement, and interview techniques that can minimize revictimization and potentially increase case advancement and improve system responses to victims of sexual

assault. Thus, this study seeks to contribute to the sexual assault case processing literature in five primary ways:

1. Produce a systematic meta-analytic literature review of studies assessing correlates of police and prosecutor decision-making in sexual assault cases,
2. Estimate the magnitude and direction of victim and case characteristics on arrest and charge decision-making,
3. Examine whether the effects of victim and case characteristics differ between police and prosecutor decision-making,
4. Combine police and prosecutor decision-making to determine which victim and case characteristics are most important to case advancement, and
5. Assess the applicability of focal concerns to understand case advancement among studies that examined both police and prosecutor decisions in sexual assault cases.

CHAPTER 2

LITERATURE REVIEW

Chapter two reviews the body of literature on police and prosecutor decision-making in sexual assault cases, as well as the influence of victim, suspect and case characteristics on the decision-making process. The chapter begins by examining research on rape myths, or stereotypes about rape cases and victims often held by criminal justice practitioners, and how case and victim characteristics can falsely shape practitioners' views and expectations of "real rape" and their perceptions of victim credibility. The chapter then moves into a discussion about the impact of rape myths and practitioner perceptions of victim credibility on police and prosecutor decision-making in sexual assault cases. Next, this chapter reviews findings from research that examined the effects of victim and case characteristics on decision-making through the lens of the focal concerns framework and underscores significant correlates of arrest and charge decisions.

In the end of this chapter, I discuss scholarship on the focal concerns perspective by reviewing the impact of focal concerns concepts on police and prosecutor decision-making (e.g., arrest and initial charge) in sexual assault cases. This review focuses on practitioner decisions to arrest, charge, and ultimately advance a case to the next stage in the justice system.

Finally, the chapter moves to a discussion on meta-analysis, and ways in which meta-analysis can address gaps in the research on criminal justice processing of sexual assault cases. Specifically, the chapter stresses the need to "take stock" of the

applicability of focal concerns to explain case advancement decisions (e.g., *arrest and charge decisions*) in sexual assault cases. I also explain meta-analytic techniques, their use in criminal justice research, and the ability of meta-analysis to take stock in a large body of research.

Rape Myth Acceptance and Sexual Assault Case Advancement

For decades, victims of sexual assault have been treated poorly and are met with skepticism by criminal justice practitioners (Brownmiller, 1975; Campbell et al., 2001; Frohman, 1991), and sexual cases are unlikely to result in arrest or prosecution (Frazier & Haney, 1996; Gregory & Lees, 1996). Indeed, studies found that less than 20% of reported sexual assaults were cleared by arrest (Morabito et al., 2019a; R. Campbell et al., 2014), and that between 18 - 61% of arrests lead to prosecution (Alderden & Ullman, 2012b). Research finds these decisions are correlated with practitioners' perceptions and attitudes towards victims, where victims often interact with police and prosecutors who question the veracity of victim allegations (Estrich, 1987). Consequently, practitioners often fail to further process cases or advise the victim to end their pursuit of charges (Galton, 1975; Kelley & Campbell, 2013; Martin & Powell, 1994).

These false perceptions and misconceptions – or rape myths – were characterized by Estrich (1987) as perceptions of a “real rape.” Specifically, Estrich described that police and prosecutor stereotypes of rape victims often shift blame from suspects towards victims, and that practitioners often believe “true” sexual assaults are ones in which (a) assaults are committed by strangers, (b) victims physically fight back, and (c) victims sustain visible injuries from the attack. Research demonstrates that many police and prosecutors accept this problematic view of sexual assault and follow these false or

stereotypical characteristics of sexual victimization when making decisions about case advancement (Brownmiller, 1975; Burt, 1980; Estrich, 1987; Lisak et al., 2010; Lonsway, 2010). Thus, if victim allegations do not fit with these stereotypes, then practitioners often question the authenticity of victim allegations (LaFree, 1981).

Indeed, studies find practitioners often have predetermined – *and false* – expectations surrounding sexual assault victims. Often these expectations are guided by rape myths, where practitioners expect the offender to use force, the victim to resist the attacker, and the victim to be attacked by a stranger, but are also influenced by factors such as whether the victim consumed alcohol or if police believed the victim had a questionable character or reputation (Beichner & Spohn, 2012; Bouffard, 2000; R. Campbell, 2008; Estrich, 1987; Kerstetter, 1990; Kingsnorth et al., 1999; Spohn & Horney, 1993).

Some research finds rape myths and stereotypes also contribute to practitioners' judgements about victim credibility, which studies find is a predictor of practitioner decision-making and case advancement (Beichner & Spohn, 2005; Spohn et al., 2001; Spohn et al., 2014). Substantial evidence exists to establish a correlation between victim credibility and case advancement (Alderden & Ullman, 2012a; Beichner & Spohn, 2005; B. Campbell et al., 2015). Researchers have examined the link between victim credibility and police and/or prosecutorial decision-making (Beichner & Spohn, 2014; Spohn et al., 2001; Alderden & Ullman, 2012a; B. Campbell et al., 2015). Victim credibility incorporates factors that impact the believability of victims (Frohman, 1991). Specifically, research shows that practitioner perceptions of a victim's moral character (e.g., history of arrest, substance abuse), alcohol use before or during the assault, and

engagement in what practitioners perceived as risk taking behavior before the assault (e.g., prostitution, hitchhiking), can all impact victim credibility (Alderden & Ullman, 2012b; Kaiser et al., 2017; Morabito et al., 2019a; Scott & Beaman, 2004; Spohn & Tellis, 2019; O’Neal et al., 2019).

Studies find that practitioner adherence to rape myths plays a role in practitioner decisions to advance cases, as evidence suggests a robust correlation between victim credibility and decisions to arrest or charge in sexual assault cases. For example, studies find that when a suspect used – or threatened to use – a weapon during the attack (Morabito et al., 2019b; Spohn & Tellis, 2019), the victim verbally or physically resisted (Alderden & Ullman, 2012ab; Morabito et al., 2019b), or when a victim sustained an injury (Morabito et al., 2019b; Spohn & Tellis, 2019; Venema et al., 2019) the odds of arrest were substantially increased. Conversely, when police officers take issue with issue with a victim’s credibility (e.g., noted a discrepancy in statement, questions about the victim’s character/reputation, victim’s criminal history) the odds of arrest significantly decrease (Alderden & Ullman, 2012b; Kaiser et al., 2017; Morabito et al., 2019a).

Scholars have used similar variables to examine prosecutor’s decision to charge – the second stage of case advancement. Sexual assault cases have higher odds of prosecution when the offender used a weapon (Burt, 1980; Frazier & Haney, 1996; McGregor et al., 2002), a victim was injured during the attack (Burt, 1980; Frazier & Haney, 1996; McGregor et al., 2002), or the victim resisted the attacker (Spohn et al., 2001; Spohn & Horney, 1993; Spohn & Spears, 1997). Additionally, cases had decreased odds of arrest when prosecutors questioned victim credibility (e.g., victim alcohol use prior or during the assault, questions about victim character/reputation, risk taking

behavior) (Beichner & Spohn, 2005; Beichner & Spohn, 2012; Spears & Spohn, 1997). In short, research has demonstrated that rape myths often explain police and prosecutor decision-making in sexual assault cases, and the concept of victim credibility is significantly linked to case advancement at both the arrest and charging stages. Accepting these myths are problematic as they often lead to practitioners misinterpreting victim behaviors and faulty decision-making, specifically the belief that “real” victims are emotionally expressive (e.g., crying, visibly distraught) fight back against and sustain injuries during the attack (B. Campbell et al., 2015; R. Campbell 2018). Literature on the neurobiology of trauma counters these rape myths and showed severe trauma has natural adverse effects on memory that hinders the ability to immediately and consistently recount details of victimization (R. Campbell, 2012; Marx et al., 2008). Additionally, although some experience “fight” or “flight” responses to trauma during victimization, research on tonic immobility found some victims subconsciously “freeze” during traumatic events. Severe trauma can trigger a neurobiological response that immobilizes victims and prevents victims from physically stopping the offender, which could explain why many survivors may not resist or suffer visible injuries resulting from the sexual assault (R. Campbell, 2012; Heidt et al., 2005; Marx et al., 2008).

Police and Prosecutor’s Decisions in Sexual Assault Cases

Prior research has shown that police and prosecutors have broad discretion when making decisions about which cases do – and do not – move forward in the criminal justice process (Frohmann, 1991; Kerstetter, 1990). Because of police officers’ role in arrest decision-making, scholars often refer to police as the “gatekeepers” to the criminal justice system, and prosecutor’s decision to charge has been referred to as the “gateway

to justice” (Kerstetter, 1990; Spohn & Tellis, 2014). Meaning, police use their discretion to establish whether a crime has been committed and then to make an arrest, and prosecutors use their discretion to determine whether to reject or accept initial charges brought by police. In this way, police and prosecutors act as the first and second formal decisions in the criminal justice system. The following sections review studies that have examined correlates of police and prosecutor decision-making.

Victim and Case Characteristics and Police Decision-making

Police officers’ pivotal role as the “gatekeepers” to the criminal justice system, means that they are initial decision-makers in process and determine whether to file a report, make an arrest, or present a case for pre-arrest prosecutorial review. When making decisions to arrest, police weigh a host of victim and case characteristics. Police consider case characteristics such as physical evidence, witness(es), physical injuries, and suspect weapon use to assist in the decision-making process. As previously mentioned, police also rely on “extralegal variables” that stem from their perceptions and stereotypes surrounding “real” sexual assault cases and credible assault victims. These variables often include both victim and case characteristics, such as victim/offender demographics, victim alcohol/substance use, prompt victim report of victimization to police, victim resistance, and victim credibility. As such, to inform the body of literature regarding sexual assault case advancement, scholars have studied the impact of these correlates on police decision-making (Bouffard, 2000; LaFree, 1981; Kaiser et al., 2017), with studies published as early as 1981 (LaFree, 1981). To assess the effects of these variables on decisions to arrest, scholars have relied on samples of sexual assault reports to code for relevant variables correlated with police decision-making (e.g., victim and suspect

demographics, victim-offender relationship, criminal histories, drug/substance use, evidence availability, weapon used, prompt victim report of victimization to police, victim injury, victim verbal and physical resistance, suspect use of force) (Alderden & Ullman, 2012ab; Beichner & Spohn, 2005; Spohn et al., 2001).

Studies examining the relationship between these variables and arrest decisions have produced mixed findings. These mixed findings could be due to different samples (e.g., jurisdictional differences, sample year(s), sample size), measurement differences, or the inclusion of different independent and control variables across studies. In terms of case characteristics, some studies found that the availability of physical evidence (Kaiser et al., 2017; Morabito et al., 2019b), witness(es) to the assault (Kaiser et al., 2017; Morabito et al., 2019b; Spohn & Tellis, 2019; O'Neal et al., 2019), victim injury (Morabito et al., 2019b; Spohn & Tellis, 2019; Venema et al., 2019), and suspect weapon use (Morabito et al., 2019b; Spohn & Tellis, 2019; Venema et al., 2019) were significantly and positively correlated to arrest decision-making. Yet, others found that availability of physical evidence (O'Neal et al., 2019), witness(es) to the assault (Alderden & Ullman, 2012a; Wentz, 2019), victim injury (Alderden & Ullman, 2012a; Scott & Beaman, 2004), and suspect weapon use (Kaiser et al., 2017; Scott & Beaman, 2004; Ylang & Holtfreter, 2019) were not significantly correlated with decisions to arrest.

A cursory search of literature found studies have been largely consistent concerning the directionality of each effect size, however findings differed on the strength of the relationship between several variables and arrest. For instance, some

found physical evidence had a very small¹ to large effect on arrest with odds ratios ranging between 1.43 (Smith, 2005) and 27.11 (Tasca et al., 2013). Results for witness(es) availability had very small to small effects on arrest and odds ratios ranged between 1.17 (Morabito et al., (2019b) and 2.14 (Venema et al., 2019). In regard to victim injury, studies have reported very small to small effects and effect sizes with odds ratios ranging from 1.02 (Kaiser et al., 2017) and 1.84 (Ylang & Holtfreter, 2019). Similarly, results for suspect weapon use ranged from very small to medium effects on odds of arrest with odds ratios ranging from 1.01 (Ylang & Holtfreter, 2019) and 2.66 (Scott & Beaman, 2004).

Studies have also reported mixed findings regarding the impact of victim characteristics on arrest decision-making. For instance, some found intimate partner relationships (Alderden & Ullman, 2012b; Kaiser et al., 2017; Morabito et al., 2019), non-stranger relationships (Alderden & Ullman, 2012b; Morabito et al., 2019b), victim race (Morabito et al., 2019; Venema et al., 2019), victim resistance (Alderden & Ullman, 2012ab; Morabito et al., 2019), and prompt victim reporting of allegations to police (Kaiser et al., 2017; Morabito et al., 2019b; Spohn & Tellis, 2019; O'Neal et al., 2019) were significantly and positively correlated to arrest decision-making. Additionally, measures of victim credibility (Alderden & Ullman, 2012b; Kaiser et al., 2017; Morabito et al., 2019b) and victim alcohol consumption (O'Neal et al., 2019; Venema et al., 2019) have been shown to significantly reduce the odds of arrest. Still, others have found insignificant correlations between intimate partner relationships (O'Neal et al., 2019;

¹ Effect sizes were described as very small, small, medium, and large using recommendations by Cohen (1988).

Spohn & Tellis, 2019), non-stranger relationships (Kaiser et al., 2017; O'Neal et al., 2019; Spohn & Tellis, 2019), victim resistance (Kaiser et al., 2017; Scott & Beaman, 2004; Spohn & Tellis, 2019; O'Neal et al., 2019), prompt victim report of victimization to police (Tasca et al., 2013), suspect race (Alderden & Ullman, 2012a; Kaiser et al., 2017), victim race (Kaiser et al., 2017; Spohn & Tellis, 2019), victim credibility (Kaiser et al., 2017; Morabito et al., 2019; O'Neal et al., 2019; Spohn & Tellis, 2019), and victim alcohol consumption (Scott & Beaman, 2004; Wentz & Keimig, 2019) to odds of arrest.

Studies produced mixed results concerning both the directionality and strength of effects for the impact of victim related variables on arrest. For instance, some found intimate partner relationships to have very small to large effects on arrest with odds ratios ranging from 1.02 (Wentz, 2019) and 7.1 (Scott & Beaman, 2004). Victim resistance was found to have very small to small effects with odds ratios ranging from 1.01 (Kaiser et al., 2017) and 1.75 (Scott & Beaman, 2004). Most studies found prompt report was positively correlated with arrest and had very small to small effects with odds ratios ranging between 1.25 (Venema et al., 2019) and 1.9 (Kaiser et al., 2017), although one study found a large negative correlation with an odds ratio of .10 (Tasca et al., 2013). In regard to victim race, the relationship between non-white victims and arrest had very small to small effects on arrest and odds ratios ranged from 1.11 (Kaiser et al., 2017) and 1.7 (Ylang & Holtfretter, 2019). Finally, research found victim credibility was both negatively correlated and positively correlated with arrest and effect sizes ranged from small to large. For example, some studies have shown that victim credibility decreased the likelihood of arrest and had very small to small effects on arrest with odds ratios ranging from .59 (Venema et al., 2019) and .81 (Smith, 2005). Conversely, others found

that victim credibility variables had very small to small effects on arrest with odds ratios ranging from 1.13 (Tasca et al., 2013) to 2.25 (Alderden & Ullman, 2012ab).

Results showed victim alcohol consumption was negatively correlated with arrest and had very small to small to robust effects and odds ratios ranged from .49 (Ylang & Holtfretter, 2019) and .81 (Smith, 2005).

As Table 1 demonstrates, the body of research is mixed regarding which correlates are most important to police decision-making in sexual assaults cases. However, studies appear to show that officers and prosecutors do weigh a host of victim and case characteristics when determining to arrest. Although evidence suggest officers rely heavily on case related factors (e.g., witness(es), physical evidence) when processing a case, evidence also suggests officers also rely on stereotypes and myths that influence perceptions about the case and victim's credibility (e.g., victim resistance, victim alcohol consumption, victim moral character/reputation). Moreover, Martin and Powell (1994) reported police are more likely to process cases in which they believe the case is "winnable" and the prosecutor will file charges. As found with prosecutors (Albonetti, 1986), police use extralegal variables to make decisions in the absences of legally relevant factors to eliminate potential uncertainty during arrest decision-making and increase the likelihood prosecutors accept charges. For instance, qualitative research shows investigators use factors such as victim behavior, moral character, substance abuse, and statement consistency when assessing victim credibility, which substantially influence officers' decisions to arrest or present a case to prosecutors (B. Campbell et al., 2015; Spohn & Tellis, 2014).

Table 1. Summary of studies on police decision-making

Study	Sample	Case Outcomes	Significant Arrest Predictors	Nonsignificant Arrest Predictors
Alderden & Ullman (2012a)	Large midwestern PD, 2003	Arrest, founded, present to prosecutor, charged	Discrepancy noted, resistance noted, victim unwilling to cooperate	Suspect race, witness present, rape kit collected, discrepancy, victim injured
Alderden & Ullman (2012b)	Large midwestern PD, 2003	Arrest	Detective gender, resistance, rape kit collected, victim character, nonstranger, intimate partner	
Bouffard (2000)	Urban/Sub urban, 2005	Arrest, closed victim unwilling to cooperate, prosecutor declined, open, unfounded	Physical description scale, prior relationship, sexual assault exam, credibility/seriousness	White victim/African American suspect, legal definition of rape, victim's age
Kaiser et al. (2017)	LAPD/LA SD, 2008	Arrest, victim cooperation at reporting, cooperation at investigation, cooperation at arrest	Attempted rape, sexual battery, more than one victim, credibility questioned, number of victim interviews, suspect intimate partner, evidence strength, number of witnesses, suspect fled, prompt reporting, suspect ID'd by victim	Victim injury, other sex offense, weapon used, threat made, more than one suspect, victim risk taking, character issues, suspect nonstranger, crime not reported by victim, victim resistance, victim or suspect black and Hispanic, victim and suspect age
Morabito et al. (2019b)	Urban, suburban, & rural, 2008-2010	Arrest, unfound, exceptional clearance, charges filed,	Black victim, nonstranger, intimate partner, questions about moral character/reputation,	Victim age, Hispanic/other victim, risk-taking behavior, suspect physically assaulted victim,

Table 1. (continued). Summary of studies on police decision-making

Study	Sample	Case Outcomes	Significant Arrest Predictors	Nonsignificant Arrest Predictors
		guilty conviction	victim mental illness, motive to lie, victim doesn't recall being assaulted, suspect used weapon, victim injured, verbal and physical resistance, prompt report, witness(es), victim cooperation in investigation, physical evidence	verbal resistance, physical resistance
O'Neal et al. (2019)	LAPD/LA SD, 2008	Arrest	Suspect black/victim Hispanic, victim consumed alcohol, suspect interviewed, victim cooperated, witness(es), prompt report, victim physically assaulted	Suspect black/victim white, suspect black/victim Hispanic, suspect black/ victim white, suspect Hispanic/victim black, suspect Hispanic/victim Hispanic, suspect Hispanic/victim white, suspect white/victim white, suspect white/victim black, suspect white/victim Hispanic, intimate partner, nonstranger, victim age, suspect age, victim credibility, physical evidence collected,

Table 1. (continued). Summary of studies on police decision-making

Study	Sample	Case Outcomes	Significant Arrest Predictors	Nonsignificant Arrest Predictors
Scott & Beaman (2004)	Western Canada, 1996	Arrest	Suspect drug/alcohol use, intimate partner, completed sexual assault	aggravated sexual assault, victim resistance Suspect age, victim age, suspect race, victim drug/alcohol use, nonstranger, weapon used, victim injury, victim resistance
Smith (2005)	Maryland, 2002-2003	Arrest	Evidence scale, number of suspects, suspect-victim relationship	victim resistance, force, non-white suspect/non-white victim, non-white suspect/white victim, white suspect/non-white victim, victim alcohol/drugs, victim age, suspect age, suspect alcohol/drugs, victim residence
Spohn & Tellis (2019)	LAPD/LA SD, 2008	Arrest, clearest by arrest, case presented to the DA for charge evaluation prior to arrest, case presented to DA after arrest and DA filed charges, case presented to DA before or after arrest and DA filed charges	Most serious charge is rape, suspect physically assaulted victim, suspect used a weapon, victim injured, reported within one hour, number of witnesses, victim cooperated, physical evidence	Victim less than 18, victim black, victim Hispanic, nonstranger, intimate partner, risky behavior, questions about character/reputation, mental illness/mental health issues, motive to lie, verbal resistance, physical resistance, both verbal and

Table 1. (continued). Summary of studies on police decision-making

Study	Sample	Case Outcomes	Significant Arrest Predictors	Nonsignificant Arrest Predictors physical resistance
Tasca et al. (2013)	Arizona City, 2003	Suspect identified, arrest	Strangers, forensic evidence available, victim made prompt report, victim lacked credibility,	Victim history of drug use
Venema et al. (2019)	Midwestern PD, 1999-2014	Unfounded, cleared, exceptionally cleared, arrest, exceptional cleared: refused to prosecute	Reported within 72hrs, detective male, detective age, victim Hispanic, victim drinking, victim injury, weapon use, witness, acquaintance, romantic partner	
Wentz (2019)	Midwestern PD, 2000-2010	Congruent charging decisions, arrest	Suspect age, physical/forensic evidence, rape kit, victim injured, suspect used weapon, reported within 24hrs,	Victim age, suspect white, witness present, victim physically resisted, risky behavior, intimate partner, acquaintance
Wentz & Keimig (2019)	Midwestern PD, 2000-2010	Arrest, forward case to prosecution	Victim cooperation, evidence, weapon use, victim injury, time to report	Victim alcohol use, relationship
Ylang & Holtfreter (2019)	LAPD/LA SD, 1982-2012	Arrest,	Offender stranger, victim suffered violence, victim used alcohol/drugs	Victim age, victim white, offender non-white, offender age, offender non-white, white offender/white victim, non-white offender/non-white

Table 1. (continued). Summary of studies on police decision-making

Study	Sample	Case Outcomes	Significant Arrest Predictors	Nonsignificant Arrest Predictors
				victim, non-white offender/white victim, multiple offenders, SAK submitted for testing, weapon used in assault, victim had sex post-assault

Victim and Case Characteristics and Prosecutor Decision-making

Because prosecutors determine whether a case enters the courts, the decision to charge has been termed the “gateway to justice” (Kerstetter, 1990). Like police, prosecutors evaluate a host of victim and case characteristics during the decision-making process (Albonetti, 1986; Spohn et al., 2001). To make sense of these decisions, Frohmann (1997) developed the downstream orientation framework which argued prosecutors consider characteristics to determine the “convictability” of a case and by taking into account how jurors and the defense attorneys may respond to a case. In line with the downstream orientation of justice, prosecutors will advance cases when they believe a guilty verdict at trial is likely, whereas cases they consider weak or unlikely to win are dropped. Perceptions of case convictability are guided by the presence of case characteristics such as physical evidence, witness(es), physical injuries, and suspect weapon use when making their decisions. In addition, prosecutors are influenced by victim characteristics, such as victim/offender demographics, victim alcohol/substance use, prompt victim report of victimization to police, and victim resistance, and perceived victim credibility. To understand how prosecutors screen cases to improve the odds of case advancement, scholars have examined the correlation between these characteristics and charge decision-making (Albonetti, 1986; Frohmann, 1991, 1997). To research this area, scholars rely on samples of sexual assault reports to review case files and code for prosecutor decision-making correlates (e.g., victim and suspect demographics, victim-offender relationship, criminal histories, drug/substance use, evidence availability, weapon used, prompt victim report of victimization to police, victim injury, victim verbal and physical resistance, suspect use of force).

Similar to police decision-making studies of which case, victim, and suspect characteristics influence prosecutor decisions to charge have also produced mixed results. As previously mentioned, mixed findings could potentially be artifacts of different samples (e.g., geographics location, sample year(s), sample size), measurement differences, or different predictors or control variables used in statistical models. For case characteristics, studies have found physical evidence (Beichner & Spohn, 2005; Spohn & Holleran, 2001), witness(es) to the assault (Beichner & Spohn, 2005; Kingsnorth et al., 1999), victim injury (Frazier & Haney, 1996; Kerstetter, 1990; Kingsnorth et al., 1999; Wentz & Keimig, 2019), and suspect weapon use (Kerstetter, 1990; LaFree, 1981; Spohn et al., 2001) significantly increase odds a prosecutor will accept charges. However, others have found physical evidence (Spears & Spohn, 1997; Spohn et al., 2001), witness(es) to the assault (Spears & Spohn, 1997; Spohn & Spears, 1996), victim injury (Spears & Spohn, 1997; Spohn & Holleran, 2001), and suspect weapon use (Spears & Spohn, 1997; Spohn & Holleran, 2001) were unrelated to decisions to levy charges.

Studies produced largely similar results on the directionality of effect sizes, however there were substantive differences regarding the strength of their impact on charging. Studies found physical evidence had very small to small effects on charging and odds ratios ranged from 1.0 (Spohn et al., 2001) and 2.4 (Spohn & Holleran, 2001). Results showed witness(es) availability had very small to large effects on charging and odds ratios ranged from 1.15 (Spohn & Spears, 1996) and 9.43 (Wentz & Keimig, 2019). Victim injury had very small to large effects and odds ratios ranged from 1.15 (Wentz & Keimig, 2019) and 8.81 (Alderden & Ullman, 2012a). Many studies found suspect weapon use had a very small to large positive correlation to arrest and odds ratios ranged

from 1.3 (Kingsworth et al., 1999) and 5.78 (Holleran et al., 2010), although Spears and Spohn (1997) reported a very small negative correlation to arrest and an odds ratio of .73.

In respect to victim characteristics, findings also appear mixed across studies. For instance, some researchers find intimate partner relationships (Spohn et al., 2001), non-stranger relationships (Beichner & Spohn, 2005), victim race (Spohn & Horney, 1993; Spohn & Spears, 1996), victim resistance (Kerstetter, 1990; Spohn & Spears, 1996), and prompt victim report of victimization to police (Beichner & Spohn, 2005; LaFree, 1981,) are significantly and positively correlated to odds of charging. In addition, measures of victim credibility (Beichner & Spohn, 2005; Spohn et al., 2001; Spears & Spohn, 1997; Spohn & Spears, 1996) and victim alcohol consumption (Chandler & Torney, 1981; Kerstetter, 1990) have been shown to significantly reduce the odds of charge.

Conversely, others have found stranger cases are more likely to be charged (Kerstetter, 1990; Weninger, 1978), while victim race (Bouffard, 2000; Frazier & Haney, 1996; Spears & Spohn, 1997), victim resistance (Spohn et al., 2001; Spohn & Holleran, 2001; Spears & Spohn, 1997), prompt victim report of victimization to police (Holleran et al., 2010; Spears & Spohn, 1997; Spohn & Holleran, 2001), and measures of victim credibility (Holleran et al., 2010; Spears & Spohn, 1997) are insignificantly related to odds of charging.

Research showed intimate partner relationships have small to large effects and odds ratios ranged from 1.09 (Holleran et al., 2010) and 7.28 (Spohn et al., 2001). Non-stranger relationships had both a very small negative effect and a very small positive effect on charging and odds ratios ranged from .76 (Spears & Spohn, 1997) and 1.42 (Spohn & Spears, 1996). Studies found that non-white victims were negatively correlated

with charging, had very small to small effects, and odds ratios ranged from .53 (Spears & Spohn, 1997) and .75 (Spohn et al., 2001). Studies showed victim resistance had very small to small effects on charging and odds ratios ranged from .57 (Spohn et al., 2001) and .95 (Spohn & Holleran, 2001). Many studies showed prompt report time had small to medium effects and increased odds of arrest with odds ratios ranging from 1.49 (Spohn & Holleran, 2001) and 3.06 (Kingsworth et al., 1999), although a single study reported a very small negative correlation with arrest and odds ratio of .73 (Holleran et al., 2010). Results showed measures of victim credibility had very small to large effects on charging and odds ratios ranged from 1.27 (Beichner & Spohn, 2005) and 8.81 (Holleran et al., 2010). Victim alcohol use had small to medium effects on charging and odds ratios ranged from .38 (Wentz & Keimig, 2019) and .57 (Spohn & Beichner, 2012).

As Table 2 shows, this line of research has mixed findings concerning variables significantly related to the odds a case will result in prosecutors accepting charges. Results show case characteristics play a role in prosecutor decision-making (e.g., physical evidence, witness(es), weapon use) and that victim characteristics and extralegal variables are correlated to charging decisions. Indeed, results showed measures associated with stereotypes and rape myths (victim credibility, victim resistance, victim reputation/moral character) influenced prosecutor's decision to charge. Evidence suggests prosecutors assess characteristics indicative of a "winnable" or convictable case when weighing their decision to charge (Albonetti, 1986; Spohn & Holleran, 2001; Spohn et al., 2001). Thus, prosecutors often use extralegal factors help reduce uncertainty during the decision-making process (Albonetti, 1986) – especially with little evidence – and influence potential case advancement. These findings align with Frohmann's (1991)

conclusion that prosecutors accept cases they view as winnable and reject difficult cases to maintain high convictions and a strong record.

Table² 2. Summary of studies on prosecutor decision-making

Study	Sample	Case Outcome	Significant Charge Predictors	Insignificant Charging Predictors
Beichner ³ & Spohn (2005)	Kansas City, Missouri (1996-98) & Miami Dade, FL (1997)	Charge	Risk-taking, moral character, prompt report, suspect age, victim injury, physical evidence, witness	White suspect/white victim, black suspect/black victim, victim age, Acquaintance/relative, IP, suspect used gun/knife
Frazier & Haney (1996)	Midwestern Metropolitan (1990-1994)	Suspects questioned, charged	Injuries, threats	Witness, verbal resistance, physical resistance, victim alcohol/drug, acquaintance rape, weapon, penetration, gang rape, white victim, white assailant
Holleran et al. (2010)	Kansas City, MI (1996-98), Philadelphia, PA (1997)	Charge	Kansas City: Physical evidence, intimate partner, Acquaintance, suspect used gun/knife, victim major injuries, risky behavior; Philadelphia: physical evidence, Acquaintance, multiple offenders	Kansas City: multiple offenders, Moral character, victim resisted, prompt report, victim age, suspect age, victim white, suspect white; Philadelphia: intimate partner, suspect used gun/knife, victim major injuries, risky behavior, moral character, victim resisted, prompt report, victim age, suspect age, victim white, suspect white, prior felony convictions
Kingsworth et al. (1999)	Sacramento County, CA (1992-94)	Charge	Victim injury, incriminating remarks, suspect arrest(s), report less	Gun/knife used, nonstranger, suspect prior felonies, accomplices, negative

² Lafree (1989) used an interval variable for the dependent variable charge, which used a seriousness score that excluded charge rejected.

³ Pooled from both jurisdictions.

Table 2. (continued). Summary of studies on prosecutor decision-making

Study	Sample	Case Outcome	Significant Charge Predictor	Insignificant Charge Predictor
			than 3hrs, report less than 4-24hrs, victim age, number of charges, victim cooperation witness(es) contradict, witness(es) support	victim characteristics, victim resistance, witness(es) in conflict
Spears & Spohn (1997)	Detroit (1989)	Charge	Moral character questioned, risk-taking, victim 13 or older	Witness, victim injured, physical evidence, suspect used gun/knife, strangers, victim screamed, physically resisted, prompt report, victim black, suspect used threat/force, suspect prior felony conviction, suspect age, suspect black
Spohn & Holleran (2001) ⁴	Kansas City (1996-98) & Philadelphia, PA (1997)	Charge, go to trial, prison sentence, length of prison term	Risk taking, moral character, suspect prior convictions, physical evidence	White victim, victim age, physically resisted, prompt report, white suspect, suspect age, suspect used gun/knife, victim injured, witnesses, Acquaintance, intimate partner, negative victim characteristics, victim resistance, witness(es) in conflict
Spohn et al. (2001)	Miami Dade, FL (1997)	Charge	Victim age, risk taking, Acquaintance/relative, intimate partner, suspect used gun/knife, victim injured	Victim white, suspect white, suspect age, physical evidence, witness, prompt report, physically resisted

⁴ Pooled from both jurisdictions

Table 2. (continued). Summary of studies on prosecutor decision-making

Study	Sample	Case Outcome	Significant Charge Predictors	Insignificant Charge Predictors
Spohn & Spears (1996)	Detroit (1970-84)	All charges dismissed, convicted, incarcerated, sentence length	Black offender/black victim, white offender/white victim, risk taking, screamed during attack, mean no. of charges,	Offender age, prior felony convictions, victim age, strangers, prior sexual relationship, physically resisted, prompt report, charge with forcible rape, vaginal penetration, more than one offender, more than one victim, offender used gun/knife, victim injured, witness, physical evidence
Spohn & Tellis (2019)	LAPD/LAS D (2008)	Arrest, clearest by arrest, case presented to the DA for charge evaluation prior to arrest, case presented to DA after arrest and DA filed charges, case presented to DA before or after arrest and DA filed charges	Victim less than 18, risky behavior, motive to lie, most serious charge is rape, suspect used a weapon, victim reported within one hour, victim willing to cooperate	Victim black, victim Hispanic, nonstranger, intimate partner, questions about moral character, mental illness/mental health issue, suspect physically assaulted victim, victim injured, verbal resistance, physical resistance, verbal and physical resistance, number of witness, physical evidence

Table 2. (continued). Summary of studies on prosecutor decision-making

Study	Sample	Case outcome	Significant Charge Predictors	Insignificant Charge Predictors
Wood et al. (2011)	Alaska State Troopers (2003-2004)	Refer case for prosecution, accept case for prosecution	Paraprofessional responder, cooperative victim, reported within 24hrs,	Isolated location, Alaska Native victim, witnesses, victim injury, aggravated offense, intimate partner relationship, victim/drug alcohol use

Focal Concerns and Practitioner Decision-making

Despite decades of research on case advancement and attrition in sexual assault cases, and although most criminal justice research on police arrest decision-making and prosecutor charge decision-making has not used theory to guide analyses, some have used the sexual stratification hypothesis and rape culture framework to explain decision-making (see Kelley et al., 2000; Spears & Spohn, 1996; O’Neal et al., 2015). The sexual stratification hypothesis stems from conflict theory and has been applied to the decision-making process and responses to victimization to explain racial and ethnic disparities (Tellis & Spohn, 2008) and the influence of victim-offender relationship (Bachman, 1998; O’Neal et al., 2019). The sexual stratification hypothesis argues those in power control sexual access based on race and ethnicity (Tellis & Spohn, 2008). It follows, Black and Hispanic men who sexually assault White women are seen by the dominant groups – White men – as disrupting and the power hierarchy. Additionally, some researchers have used the rape culture framework to understand social environments where sexual violence is tolerated and accepted by people as normal (see Buchwald et al., 1993; O’Neal & Hayes, 2020). This normalized culture may shape people’s views and negatively influence perceptions about sexual victimization and drive misguided stereotypes about rape victims (Burt, 1980).

That said, however, my review focuses on criminal justice scholarship, which has begun to apply the focal concerns perspective to help explain and understand correlates of decision-making at the arrest and charging stages. Specifically, researchers have used the framework to explain prosecutorial decision-making in sexual assault cases (Beichner & Spohn, 2012; Spohn et al., 2001), while others have recently expanded the framework

to explain police decision-making in taser usage (Crow & Adrion, 2011), time lapses in serving arrest warrants (Johnson et al., 2015), and unfounding cases and identify false reports (Spohn et al., 2014).

The construction of the focal concerns perspective was inspired by previous research by Albonetti (1986, 1987), which argued practitioners make decisions based on a bounded “reality” (Albonetti, 1991, p. 249), specifically when the case lacks physical evidence and practitioners seek to minimize “uncertainty” that surrounds the case.

Albonetti (1991) also incorporated work from structural organization theory and argued fully rational decisions are made only when the decision-maker has the “knowledge of all possible alternatives” (p. 248) and stated practitioners make decisions based on “a reality that is the product of habit and social structure” (Albonetti, 1991, p. 249), where judges’ sentencing decisions and prosecutors’ decisions to charge are guided by characteristics of offenders linked to recidivism (Albonetti, 1986, 1987, 1991). Albonetti argued judges seldom have complete information during the decision-making process and must rely on perceptual shorthand, past experiences, stereotypes, and prejudice from their habits and social structure. For instance, a judge is more likely to issue a longer sentence when an offender had prior arrests, used a weapon, or caused a physical injury.

Following this line of thinking, Steffensmeier et al. (1998) conceptualized the focal concerns framework by expanding Albonetti’s work to include concepts that encompassed additional offender and organizational characteristics. Steffensmeier and colleagues’ primary goal was to create a theory that could make sense of how judges made sentencing decisions. Accordingly, Steffensmeier and colleagues’ original focal concerns framework contains three primary concepts, including (a) culpability and

offender blameworthiness, (b) the perceived dangerousness of the offender and need for community protection through incapacitation and general deterrence, and (c) practical and resource constraints faced by decision-makers in the criminal justice system (Steffensmeier et al., 1998). In addition, focal concerns argues that judges often have limited knowledge regarding an offender's criminal background, personality, or moral character, and must also make quick and decisive decisions based on limited information and resources (e.g., time, court cost). When time or information is limited to fully inform decisions, judges often use a "perceptual shorthand" based on an evaluation of extralegal variables (e.g., offender race, sex, age) to determine the offender's perceived blameworthiness and threat to society. Based on these concepts, judges make an assessment of how likely an offender is to commit further crimes based on stereotypes concerning "who is dangerous and who is not", while taking into account constraints such as potential strain on correctional facilities, incarceration costs, offender needs, and political implications during decisions (Steffensmeier et al., 1998, p. 767). It is important to stress extralegal characteristics such as victim race and suspect race are variables that should not be considered during the legal decision-making process. However, research has found these variables may influence decisions (Kelley et al., 2020; Spohn & Tellis, 2008). For instance, research finds decision-making is often based on the victim-racial-ethnic dyad, and white victim who assault non-white victims are more likely to receive more lenient treatment and non-white suspects who assault white victims receive harsher treatment (Kelley et al., 2020; O'Neal et al., 2016). In addition, some evidence suggest Black-on-Black sexual assaults may be viewed as less worthy of resources from the legal system and experience higher case attrition (Kelley et al., 2020)

Sentencing research using focal concerns has included variables such as race, ethnicity, and criminal history to better understand judges' sentencing decisions (Franklin & Henry, 2020; Johnson & Bestinger, 2009; Steffensmeier et al., 1998), and has determined that judges sometimes view specific groups as more dangerous or blameworthy for their crime (Johnson & DiPietro, 2012). Indeed, studies have shown non-white offenders often receive harsher sentences compared to white offenders (Alvarez & Bachman, 1996; Franklin, 2013; Franklin & Henry, 2020; Mitchell, 2005; Ulmer, 2012), and that young, black males are often sentenced the harshest (Spohn & Holleran, 2001; Steffensmeier et al., 1998). Scholars have also found criminal history and offense severity increase sentencing length imposed by judges (Franklin, 2017; Franklin & Henry, 2020; Spohn, 2000; Zatz, 2000)

Researchers have furthered the application of focal concerns to other critical decision points in the justice system (Hartley et al., 2007). For instance, Hartley et al. (2007) discussed how previous studies have conceptualized and operationalized focal concerns variables, as well as explored how recent studies have used the framework to explain police and prosecutor decisions. Hartley and colleagues provided clarity to the framework by suggesting specific measures for each concept and ways to improve concept measurement. The authors argued that, in its original form, the focal concerns framework produced “no set of testable propositions; most hypotheses that have been derived from this work have been extended over time” (p. 73) and thus attempted to address shortcomings of focal concerns. Their argument provided several limitations of focal concerns and included suggestions to move focal concerns research forward. First, one shortcoming was that focal concerns lacked established measurements for concepts.

As such, the authors used factor analysis to statistically examine the relationship between independent variables and determine variables that could be collapsed within a concept. Second, Hartley and colleagues suggested that some variables could be used to measure multiple concepts, such as criminal history, which can be used to explain blameworthiness and the need for protection of the community. Factor analysis helped provide clarity to concept measurement and found criminal history loaded onto the factor protection of the community rather than suspect blameworthiness, and suggested using criminal history to measure protection of the community. Third, Hartley et al. suggested the need to fully operationalize and explore perceptual shorthand and practical constraints. Initially, scholars primarily used Pennsylvania Sentencing Commission data to study sentencing decisions, which lacked variables needed to study perceptual shorthand and practical constraints. Thus, the authors used Federal Sentencing Commission data that allowed for a “fuller conceptualization, operationalization, and thus, a more complete test of the focal concerns perspective” (Hartley et al., 2007, p. 64). In this way, Hartley et al. (2007) helped advance conceptualization and operationalization of focal concerns concepts and to produce a framework for future researchers using the perspective.

Following Hartley and colleagues work, scholars have expanded on focal concerns to explain prosecutor decision-making (Beichner & Spohn, 2012; Spohn et al., 2001). For example, Spohn et al. (2001) argued when making charging decisions in sexual assault cases, prosecutors and judges weigh similar factors, specifically those related to offense severity, offender’s criminal history, and suspect culpability during the decision-making process. It follows that, higher odds of charges exist when factors

corroborate a victim's claim and indicative of a serious offense. Diverging slightly from Steffensmeier et al. (1998), Spohn and colleagues (2001) argued prosecutors fail to consider the same practical constraints and consequences of judges. Unlike judges, who consider strain on correctional facilities, incarceration costs, offender needs, and political implications during decisions, prosecutors are more focused on a jury finding the defendant guilty (Beichner & Spohn, 2012; Spohn et al., 2001). As such, prosecutors have relied on a perceptual shorthand based on stereotypes and myths about sexual assault cases and victims, while also attempting to reduce uncertainty regarding case outcomes (Spohn et al., 2001). Included in perceptual shorthand developed by prosecutors are both factors that blame victims (e.g., risk-taking behavior, moral character) and victim characteristics (e.g., prompt reporting of victimization to police, victim resistance) that are perceived to affect juror decision-making.

Scholars that have used focal concerns measures to explain prosecutorial decision-making find support for the framework (Beichner & Spohn, 2005; Brady & Reyns, 2020; Holmes & D'Amato, 2020; Spohn & Tellis, 2019). For instance, Brady and Reyns (2020) examined prosecutors' charging decisions in stalking cases and found support for protection of the community (e.g., pursued victim in a public location) and practical constraints (e.g., evoked fear in the victim). Their findings revealed that prosecutors were 230% more likely to charge offenders that pursued victims in public and were 290% more likely to charge offenders that evoked fear in victims. Additionally, Stemen and Escobar (2018) examined prosecutors' decision to reject charges in 318,000 felony and misdemeanor cases and found support for offender blameworthiness (e.g., offense seriousness, number of charges) and perceptual shorthand (e.g., offender race,

offender age). The authors found more serious offenses reduced likelihood of charges rejected by 5% and greater number of charges reduced likelihood of charges rejected by 16%. Offender race also had a statistically significant effect on case dismissal, and case that involved non-white suspects were 3% less likely to result in the rejection of charges. Specific to sexual assault cases, Beichner and Spohn (2005) found support for offender blameworthiness (e.g., victim injured) and practical constraints (e.g., physical evidence available, witness(s) present) and reported prosecutors were 141% more likely to charge when a victim was injured, 161% more likely to charge when physical evidence was available, and 167% when a witness(es) was present. Spohn & Tellis (2019) found support for protection of the community demonstrating that prosecutors were 220% more likely to charge when a suspect used a weapon during the incident.

Similar to the application of focal concerns to prosecutorial decisions, recent policing scholars have used the perspective to explain officer decision-making across various outcomes (e.g., search vehicle, use a taser, submit sexual assault kit) (R. Campbell & Fehler-Cabral, 2018; Crow & Adrion, 2011; Higgins et al., 2012; Ishoy & Dabney, 2017; Johnson et al., 2015; Spohn et al., 2014; Tillyer & Hartley, 2010). Crow and Adrion (2011) used focal concerns to explain officers' decision to use taser in use of force incidents and found evidence that protection of the community (e.g., perceived dangerousness), perceptual shorthand (e.g., suspect sex and race), and practical constraints (e.g., taser policy). After controlling for situational factors and suspect characteristics, the odds of officers using a taser decreased by 60% in situations involving a suspect who used physical or weapon-related resistance compared to verbal resistance. This provides evidence that officers consider perceived level of dangerousness when met

with resistance. Officer taser use increased by 99% for non-white suspects and 362% for male suspects. Lastly, new agency policy (e.g., taser training) reduced taser usage by nearly 60%. Higgins and colleagues (2012) also used focal concerns to explain officers' decision to search a vehicle during a traffic stop and found the decision was strongly and positively correlated with blameworthiness (e.g., contraband in plain view, smelled drug odor). In fact, officers were 56% more likely to arrest suspects when offender blameworthiness variables were found in a traffic stop.

Focal Concerns and Practitioner Decision-making in sexual assault cases

Academics have relied on focal concerns to explain practitioner decision-making at multiple stages (e.g., arrest, charging) in sexual assault cases. For nearly 20 years scholars have used the focal concerns perspective to explain prosecutor decision-making in sexual assault cases (Beichner & Spohn, 2005, 2012; Spohn et al., 2001; Wentz, 2019), and more recently scholars have begun to use focal concerns concepts and variables to study police decision-making in sexual assault cases (Kaiser et al., 2017; Spohn & Tellis, 2019; Venema et al., 2019; Wentz 2019, Ylang & Holtfreter, 2019). Regarding sexual assault investigations, scholars have used focal concerns to determine how focal concerns variables influence police decision-making (O'Neal & Spohn, 2017; Spohn & Tellis, 2019). Scholars used the focal concerns perspective to describe suspect blameworthiness as harm caused to the victim, protection of the community as the severity or heinousness of the assault, practical constraints as factors beyond the control of practitioners, and perceptual shorthand as extralegal variables practitioners disregard and usually fit with rape myth acceptance. Still, until only recently have scholars operationalized focal concerns variables and addressed measurement deficiencies (Hartley et al., 2007). Thus, I

adapted work from Tillyer and Hartley (2010) and O’Neal and Spohn (2017) to guide definitions and operationalizations of focal concerns variables and are displayed.

Tillyer and Hartley (2010) first defined suspect blameworthiness as the suspect’s level of culpability and seriousness of the crime. Second, protection of the community was defined as protecting the community from repeat offenders. Third, practical constraints was defined as factors that increase the probability of case advancement. Forth, perceptual shorthand was defined as extralegal factors considered during decision-making. Additionally, O’Neal and Spohn (2017) were the first to formally operationalize focal concerns variables to explain decision-making in sexual assault cases and operationalized (a) *suspect blameworthiness* using variables that measured whether the suspect previously sexually assaulted the victim, suspect previously physically assaulted the victim, victim was injured at the time of assault, suspect physically assaulted victim at time of incident, and victim resisted (verbally, physically, or both); (b)⁵ *protection of the community* was measured by indicated whether the suspect used some type of weapon; (c) *practical constraints* was captured by indicating whether some physical evidence collected, the suspect was interviewed by police, the victim cooperated with investigation, there was at least one witness to the incident, the victim reported within one hour, and the suspect and victim have children; and (d) *perceptual shorthand* was measured by measuring suspect/victim race – suspect non-white, victim non-white –

⁵ Although O’Neal and Spohn did not include criminal history in their analysis, Hartley et al. (2007) suggested using offender criminal history as a measure of protection of the community. However, no studies were identified that examined the correlation between offender criminal history and arrest.

victim consumed alcohol prior to or during incident, suspect consumed alcohol prior to or during incident, victim had motive to lie, and suspect and victim married. When determining correlates of practitioner decision-making in sexual assault cases, researchers have examined several variables that fit with focal concerns measures provided by O'Neal and Spohn (2017), but these authors were the first to explicitly place these measures in the focal concerns perspective.

I used the work of Tillyer and Hartley (2010) and O'Neal and Spohn (2017) as a guide to define and measure focal concern variables. Research found variables related to suspect blameworthiness were significantly and positively correlated with practitioner decision to arrest and charge (Alderden & Ullman, 2012ab; Frazier & Haney, 1996; Kerstetter, 1990; Kingsnorth et al., 1999; Morabito et al., 2019b; Spohn & Tellis, 2019; O'Neal et al., 2019; Venema et al., 2019). Yet, others found variables related to suspect blameworthiness were insignificant correlates of arrest and charging (Kaiser et al., 2017; Scott & Beaman, 2004; Smith, 2005; Spears & Spohn, 1996; Spohn & Holleran, 2001; Spohn et al., 2001). Some research found a significant and positive correlation between variables that measured the need for protection of the community and arrest and charging (Kerstetter, 1990; LaFree, 1981; Morabito et al., 2019b; Spohn et al., 2001; Spohn & Tellis, 2019; Venema et al., 2019), although others report an insignificant relationship (Holleran et al., 2010; Kaiser et al., 2017; Kingsworth et al., 1999; Scott & Beaman, 2004; Ylang & Holtfreter, 2019). Research found a significant and positive correlation between variables related to practical constraints and arrest and charging (Beichner & Spohn, 2005; Kaiser et al., 2017; Kingsnorth et al., 1999; LaFree, 1981, 1989; Morabito et al., 2019b; Spohn & Holleran, 2001; Spohn et al., 2001; Spohn & Tellis, 2019),

however others reported an insignificant relationship between variables associated with practical constraints and arrest and charging (Alderden & Ullman, 2012a; Holleran et al., 2010; O’Neal et al., 2019; Spears & Spohn, 1997; Spohn & Holleran, 2001; Tasca et al., 2013; Wentz, 2019). Lastly, research found variables related to perceptual shorthand were significantly and positively correlated to arrest and charging (Alderden & Ullman, 2012b; Beichner & Spohn, 2005; Morabito et al., 2019b; O’Neal et al., 2019; Spohn et al., 2001; Spohn & Horney, 1993; Spohn & Spears, 1996; Venema et al., 2019), but others found an insignificant relationship between variables related to perceptual shorthand and arrest and charging (Alderden & Ullman, 2012a; Bouffard, 2000; Frazier & Haney, 1996; Holleran et al., 2010; Kaiser et al., 2017; Scott & Beaman, 2004; Spears & Spohn, 1997; Spohn & Holleran, 2010; Wentz & Keimig, 2019). Additionally, research shows measures of victim credibility (Beichner & Spohn, 2005; Spohn et al., 2001; Spears & Spohn, 1996, 1997) and victim alcohol consumption (Chandler & Torney, 1981; Kerstetter, 1990; O’Neal et al., 2019; Venema et al., 2019) were significantly and negatively correlated with reduced odds of case advancement. Still, others reported an insignificant relationship between variables related to victim credibility (Holleran et al., 2010; Kaiser et al., 2017; Morabito et al., 2019b; O’Neal et al., 2019; Spears & Spohn, 1997; Spohn & Tellis, 2019) and victim alcohol consumption (Scott & Beaman, 2004; Smith, 2005; Wentz & Keimig, 2019) with arrest and charging.

The Current Study and the Need for a Systematic Meta-Analytic Review

Some empirical evidence exists to support focal concerns as a framework to explain police and prosecutor decision-making in sexual assault cases. Indeed, a review of the literature identified several studies that found variables related to the focal

concerns perspective were significant correlates of case advancement. Overall, however, the studies fail to reach a consensus, as many studies report insignificant results and weak correlations between focal concerns measures and police officers' decision to arrest. Because differences in findings across studies, a systematic review is needed to condense the literature and a meta-analysis is needed to assess the current state of police and prosecutor sexual assault decision-making literature. This is the first study to attempt to evaluate the magnitude and direction of the relationships between focal concerns variables and practitioner decision-making across all studies, and determine which correlates are most important to case advancement in sexual assault cases. Identifying the most important correlates of case advancement is required to inform evidenced based policy, police training and educational topics (e.g., rape myths and misconceptions, evidence processing, maintaining victim engagement, interview techniques, neurobiological trauma), help reduce case attrition during arrest and charging, and to improve criminal justice system responses to victims of sexual assault.

Based on this cursory review of the literature, studies appear to find support for the ability of focal concerns to explain arrest and prosecutorial decision-making in sexual assault cases. Each focal concern concept contained measures significantly correlated with arrest and odds of charging. However, the overall review produced mixed findings for the impact of focal concerns variables on arrest and charge decision-making and resulted in many studies reporting insignificant and weak associations between key variables to arrest and charging. As such, no study has systematically reviewed the sexual assault decision-making literature, and none have used meta-analysis to condense and evaluate correlates of case advancement through the arrest and charging stages. This

omission is important because scholars have not calculated the effects of these focal concerns at each stage of criminal justice processing (e.g., arrest, charging), and none have combined the effects of both arrest and charging decisions to determine the strongest predictors of overall case advancement.

Meta-Analysis

First developed in the 1970s, meta-analysis is a statistical approach to synthesize literature without the innate biases associated with narrative reviews (Hunt, 1997). Because of its ability to “take stock” of literature (Cullen, 2005) and help determine what studies “really say” about a topic (Hunter & Schmidt, 2004; Lipsey & Wilson, 2001), meta-analysis has become widely used in criminology and criminal justice (Turanovic & Pratt, 2020). The approach can gather large amounts of information on a topic and then synthesize results across all studies. In addition, meta-analysis uses effect sizes across studies to examine the associating a variable(s) (e.g., intervention, correlates) on outcomes. According to Johnson (2010), meta-analysis includes five steps: “(1) formulating the problem, (2) collecting the data, (3) evaluating the data, (4) synthesizing the data, (5) presenting the findings” (p. 73). Using meta-analysis allows for several advantages, such as examining the statistical relationship between variables using effect sizes, assessing the relationship strength while controlling for methodological variation, the ability to replicate meta-analysis, and ability to update meta-analysis results when new studies are available (Pratt & Cullen, 2001).

Meta-analysis is a means to collect quantitative research on an interventions, programs, or correlates and calculate these to produce a single effect size and to better evaluate policy implications (Johnson, 2010). Meta-analysis can combine relevant studies

to provide a single conclusion, while also containing greater statistical power because of its ability to analyze multiple studies simultaneously. Rather than count p-values across studies, meta-analysis systematically assess findings from an entire body of research and helps establish statistical significance, directionality, and strength an intervention or correlate(s) has on an outcome.

Although meta-analysis was initially developed and used within education and psychology (Cooper et al., 2019; Koricheva et al., 2013), the technique has become more common within criminal justice and criminology and helped to “take stock” of literature on many topics (Cullen, 2005; Farrington & Welsh, 2008; Wells, 2009). In fact, a recent Google Scholar search by Turanovic and Pratt (2020) using the terms “meta-analysis” and “criminology” or “criminal justice” found over 110,000 hits, many of which were published after 2010. In criminal justice and criminology, meta-analysis has been most salient in studying the effects of correctional crime control strategies (Andrews et al., 1990; Hanson & Bussiere, 1998; Lipsey & Wilson, 1998), effectiveness of policing approaches (Braga et al., 2014; Braga & Weisburd, 2012), and crime prevention strategies (Farrington & Welsh, 2003; Welsh & Farrington, 2009; Wilson et al., 2001). By summarizing these bodies of literature, criminal justice and criminology scholars have used meta-analysis to synthesize and assess the findings of program evaluations (Bennett et al., 2007; Piquero et al., 2016; Schmucker & Losel, 2015), policing interventions (Braga et al., 2014; Braga & Weisburd, 2012), and the empirical status of criminological theories (Paternoster, 1987; Pratt et al., 2006; Pratt et al., 2010; Pratt & Cullen, 2000, 2005).

In many academic fields it is often difficult to reach conclusions on a specific research question or hypothesis, as many studies use varying methodologies, analytic strategies, diverging findings and conclusions, and because pertinent studies are often tough to locate throughout different journals and grey matter (Denney & Tewksbury, 2013; Mazerolle et al., 2013; Turanovic & Pratt, 2020; Wickramasekera et al., 2015). Furthermore, issues regarding the “file drawer problem” (i.e., researchers only publishing significant findings) (Hunter & Schmidt, 2004) and methodological differences across studies make it difficult to determine the “real findings” (see Booth et al., 2016). Additionally, only using narrative reviews causes unique problems, especially with issues concerning how reviewers determine studies to include and exclude based on their preferences (Hunt, 1997), and that many narrative reviews fail to reach substantive conclusions other than the need for future studies (Kempf, 1993, 2019). Meta-analysis, however, synthesizes empirical results across all quantitative studies and thus helps overcome many review biases and allows for objective and precise estimates, despite variations in methodologies, analytic strategies, diverging findings and conclusions. In this way, meta-analysis results can present a clearer picture on what research “really says” about a topic (Hunter & Schmidt, 2004; Lipsey & Wilson, 2001).

The current study follows work of previous meta-analysis studies by “taking stock” (Cullen, 2005) of the literature regarding decision-making in sexual assault cases and by assessing the empirical support of the focal concerns perspective in such cases. Because of mixed findings across studies on the topics of police officers’ decision to arrest in sexual assault investigations and prosecutors’ decision to charge in sexual assault cases, a meta-analysis is needed to assess the current state of the literature

regarding case advancement in sex crime cases. The current study conducts a systematic review to synthesize the literature and to estimate the magnitude and direction for the relationships between focal concerns variables and police and prosecutor decision-making using meta-analysis. By doing so, the study hopes to identify the most important focal concerns for police and prosecutor decision-making, as well as determine what focal concerns are most important to overall case advancement in sexual assault cases. The goal of this meta-analysis is to help inform evidence-based policies and practices and help enhance practitioner training and educational topics (e.g., rape myths and misconceptions, evidence processing, maintaining victim engagement, sexual assault dynamics, interview techniques, neurobiology of trauma). Thus, assessing the strongest correlates of case advancement can inform evidence-based interventions aimed at improving police and prosecutor responses to sexual assault victims and potentially reduce case attrition.

CHAPTER 3

METHODOLOGY

To my knowledge, no studies have performed a systematic meta-analytic review of the literature examining police and prosecutor decision-making in sexual assault cases. Thus, using operationalizations of focal concerns variables adapted from O’Neal and Spohn (2017), this study conducted a systematic review of the literature dating back to 1981. The study also conducted meta-analyses to evaluate the effects of each focal concern variable on police officers’ decision to arrest or present a case to a prosecutor, prosecutors’ decision to charge, and both arrest/present and charging decisions aggregated. This review sought to contribute to our understanding of criminal justice practitioners’ decision-making in sexual assault cases by:

1. Producing a systematic meta-analytic literature review of studies assessing correlates of police and prosecutor decision-making in sexual assault cases,
2. Estimating the magnitude and direction of victim and case characteristics on arrest and charging,
3. Examining whether the effects of victim and case characteristics differ between police and prosecutor decision-making,
4. Combining police and prosecutor decision-making to determine which victim and case characteristics are most important to case advancement, and

5. Assessing the applicability of focal concerns to understand case advancement among studies that examined both police and prosecutor decisions in sexual assault cases.

The review used guidelines published by the Campbell Collaboration of Systematic Reviews (Steering Group of the Campbell Collaboration, 2019) to code information on focal concerns variables across all relevant police and prosecutor decision-making studies. The meta-analysis used this information to calculate the average effect of each focal concern variable on decision-making outcomes across all quantitative studies. This process provided the mean effect for each focal concerns variable on police decision-making, prosecutor decision-making, and an aggregated model that combined police and prosecutor decision-making. In addition, the meta-analyses presented the overall magnitude and direction of each effect size for all focal concerns variables (Borenstein et al., 2011; Haidich, 2010; Lipsey & Wilson, 2001; Sullivan & Feinn, 2012). Rather than rely on mixed findings across studies of decision-making in sexual assault cases, this review “takes stock” of the mixed findings across studies and produced a single and more precise effect size to measure the magnitude of the relationship between each focal concerns variable practitioner decision-making (Cullen et al., 2006; Haidich, 2010; Turanovic & Pratt, 2020).

Sample

The review sample included all studies that quantitatively assessed correlates of police officers decision to arrest or present a case for prosecutorial review prior to arrest and prosecutors decision to charge. These two decision-making outcomes are similar (see Spohn & Tellis, 2019), but are substantively different than other police decisions (e.g.,

interview suspect, unfound a case, exceptionally clear a case). As such, studies analyzing clearance status (e.g., open investigation, unfounded, exceptionally cleared) and earlier measures of investigative effort (e.g., interview suspect, identify a suspect) were excluded from the review. In addition, subsamples of intimate partner assault were excluded from the analysis. Evidence suggests these cases of intimate partner assault may be handled different than other cases by the legal system and be trivialized, viewed as a “domestic squabble”, a private incident between domestic partners, and less severe (Bergen, 2004; O’Neal et al., 2015). For instance, Accordingly, the review contains studies that:

1. Included cases of reported, investigated, and prosecuted as sexual assault.
2. Included a general sample of sexual assault cases and not only a subsample (e.g., intimate partner sexual assaults) that occurred anywhere and not only the United States and was not restricted by age of the sample,
3. Quantitatively assessed police’s decision to present/arrest and prosecutors’ decision to charge as outcome variables,
4. Measured the effects correlates used in the focal concerns framework on police’s decision to present/arrest and prosecutors’ decision to charge,
5. Presented enough statistical information to compute at least one effect size from a multivariate⁶ model.

⁶ Bivariate models will be included and assessed in future studies. This study included only multivariate models that take into account other independent variables and present more conservative estimates.

Search Strategies

Because I reviewed different participants (e.g., police and prosecutors) and outcomes (e.g., present/arrest, charge), the review used two separate exhaustive search strategies to locate police and prosecutor decision-making studies. In both cases, I searched the online databases (1) ProQuest Dissertation and Theses Global, (2) Criminal Justice Abstracts, (3) PsychINFO, and (4) Sociological Abstracts, because these are the most relevant databases used in criminal justice and criminology. Initially, the search was kept intentionally broad, but after searches resulted in high numbers of unrelated studies, a more focused search command was used and resulted in more pertinent studies. The search command for police decisions used AB(sexual assault OR rape) AND (arrest) AND (deci* OR discretion) AND (law enforcement OR police OR investigator) and occurred in January 2020 and resulted in 1,672 potential studies, while the literature search for prosecutor decision-making occurred in January of 2020, used the search command AB (sexual assault OR rape) AND (charg* OR prosecut*) AND (deci* OR discretion) AND (prosecutor OR attorney), and resulted in 1,974 studies. In addition, to further reduce the likelihood of missing relevant studies, article references were surveyed to identify additional studies. The eligibility screening was a two-step process. First, every unique article was screened by title and abstract and was only excluded if the title and abstract were clearly irrelevant or failed to meet study inclusion criteria. The final step was a full-text screening that evaluated whether the study met each specific inclusion criteria. If the study passed both steps, it was included in the analysis.

Reliability of Coding

It is critical to maintain coding fidelity to produce reliable results. Thus, a coding sheet modified from Higginson et al. (2018) was used to code the sample of articles for both police and prosecutor decision-making. The coding sheet included 25-items and was managed using Microsoft Excel. The full 25-item coding sheet is provided in Appendix A, and was comprised of twelve methodological items (e.g., data source, sample location, sample frame), nine statistical analysis items (e.g., sample size, outcome variables, predictor variables), and the variables measuring the four focal concerns categories in each study. Once studies were screened by titles and abstracts, I completed the coding process. In order to maintain a high level of coding consistency and to calculate inter-rater reliability, five articles were randomly selected and coded independently by two researchers and compared for coding consistency. The Yeaton-Wortman method was used to calculate inter-rater reliability (Yeaton & Wortman, 1993). As such, the number of agreements was divided by the total number of coding agreements. For studies on police decision-making, this resulted in agreement of 87% and is an acceptable level. Likewise, the same process was used to code the prosecutor study sample and resulted in a high 85.5% coder agreement and is an acceptable level. To resolve coding discrepancies, the two researchers met to discuss and resolve such differences (Yeaton & Wortman, 1993). Once differences were resolved, I then coded all studies using the coding scheme produced by this process.

Measures

To assess the applicability of focal concerns to police and prosecutor decision-making in sexual assault cases, this review analyzed variables that measured all four focal

concerns concepts, which includes *suspect blameworthiness*, *community protection*, *practical constraints*, and *perceptual shorthand* variables. To accomplish this, the review used Tillyer and Hartley (2010) and O'Neal and Spohn (2017) as a guide, and when needed adapted each of their focal concerns operationalizations to fit with the measures used in previous studies. O'Neal and Spohn's initial operationalizations incorporated at least one variable measuring each focal concerns concept. O'Neal and Spohn measured suspect blameworthiness using measures including whether the suspect previously sexually assaulted the victim, suspect previously physically assaulted the victim, victim was injured at the time of assault, suspect physically assaulted victim at time of incident, and victim resisted (verbally, physically, or both). The authors measured the need for community protection using measures of whether the suspect used some type of weapon. Practical constraints and consequences was measured using some variables including physical evidence collected, suspect was interviewed by police, the victim cooperated with the investigation, there was at least one witness to the incident, the victim reported within one hour, the suspect and victim have children. Lastly, they measured perceptual shorthand variables including suspect non-white, victim non-white, victim consumed alcohol prior to/during incident, suspect consumed alcohol prior to/during incident, victim had motive to lie, and suspect and victim married.

On several occasions not enough studies used the exact same variable offered by O'Neal and Spohn to warrant a meta-analysis (e.g., suspect and victim have children, suspect previously sexually assaulted the victim, suspect was interviewed by police) and in such cases I was unable to include each of these variable in the analysis. In addition, several variables proposed by O'Neal and Spohn were slightly modified to become more

inclusive and increase total effect sizes. Specifically the review measured prompt report time within 72 hours of the assault rather than one hour, suspect and victim married was changed to intimate partner relationships, and a victim credibility measure was included as variable of perceptual shorthand. These variable modifications were made based on measurement tendencies across previous studies to ensure the review was as inclusive as possible and that effect sizes were not unnecessarily excluded from the analysis (see Turanovic & Pratt, 2020). For example, if the review included O’Neal and Spohn’s prompt report time within one hour, then slightly dissimilar variables (e.g., within seven hours or 72 hours) would be excluded and number of effect sizes reduced.

For the current review, *suspect blameworthiness* was operationalized using victim resistance (i.e., victim physically or verbally resisted the assault) and victim injury (i.e., physical injuries were noted on the victim). Victim resistance includes whether the victim verbally resisted or physically resisted – or both verbally and physically resisted – their attacker. Second, *protection of the community* included whether the suspect used, or attempted to use a weapon during the assault. Third, physical evidence, prompt report, witness(es), and victim cooperation were included as measures of *practical constraints*. Physical evidence included any variable measuring indicating the presence of physical evidence in the case (DNA, fingerprints, clothing). Prompt report included any case in which the victim reported the incident to an officer or medical professional within 72 hours of the assault, and victim cooperation meant that police perceived the victim was engaged with the investigation.

Finally, *perceptual shorthand* was measured using several extralegal variables including the victim-offender relationship (non-stranger and intimate partner

relationships), victim and suspect age, victim and suspect race, and victim credibility. Victim credibility was measured uniquely by a large number of studies. For instance, some measured victim credibility by only using victim discrepancies, victim had motive to lie, victim engaged in risk-taking behavior, victim credibility was questioned, or victim was a prostitute. Because of this, the review created a composite measure to analyze the combined effects of victim credibility on present/arrest and charge decision-making (Pratt & Cullen, 2000). Specifically, we measured victim credibility using widely accepted definitions for credibility issues, including victim drug/alcohol use surrounding the incident, history of drug/alcohol use, history of prostitution, engagement in risk-taking behaviors, police perceptions of moral character, and inconsistent victim statements to criminal justice personnel (Campbell, 2015; O'Neal & Spohn, 2017; Spohn et al., 2001).

Moderating Variables

Several moderator analyses were conducted in models that examined police decisions to arrest, prosecutor decisions to charge, and combined models assessing both arrest and charging decisions.. For example, one moderator analysis examined the effect of the study years, while another assessed the study sample size to determine if these characteristics moderated the effect size estimates. Sample year (i.e., the year the sexual assault was investigated) was analyzed to determine if the year moderated effects. It is possible changes over time may influence the association between correlates and decision-making. For instance, it is possible the way sexual assault is investigated may have changed over time. I included study sample size as a moderator to determine if larger samples moderated effects.

Risk of Bias

A risk of bias coding sheet was adapted from work by Higginson et al. (2018), which included a string of questions presented in Appendix A. These items were modified and evaluated the study quality regarding sampling procedures, measurement of variables, sample years, sample location, and model outputs (e.g., reported model performance measures). Studies were not scored based on these items and studies were not removed based their risk of bias assessment.

Table 3. Focal concerns definitions and measurement.

Focal concerns	Definition	Measures
Suspect blameworthiness	The suspect's level of culpability and seriousness of the crime	Suspect previously sexually assaulted the victim Suspect previously physically assaulted the victim Victim was injured at the time of assault Suspect physically assaulted victim at time of incident Victim resisted (verbally, physically, or both)
Protection of the community	Protection of the community from repeat offenders	Suspect used some type of weapon during the assault
Practical constraints and consequences	Factors that increase the probability of case advancement	Physical evidence collected Suspect was interviewed by police Victim cooperated during the investigation At least one witness to the incident Victim reported within one hour The suspect and victim have children
Perceptual shorthand	Extralegal factors considered during decision-making	Suspect non-white Victim non-white Victim consumed alcohol prior to/during incident Suspect consumed alcohol prior to/during incident Victim had motive to lie Suspect and victim married

Statistical dependence across studies

Statistical dependence is a major concern in meta-analysis and creates the risk of producing biased and inflated results (Lipsey & Wilson, 2001). In the past, traditional meta-analysis required each effect size to be unique and independent from each other (January et al., 2011; Wilson & Lipsey, 2006), which was often difficult because several studies shared a common data source collected in the same year(s). For instance, multiple studies used arrest data from the Los Angeles Police Department and Los Angeles Sheriff's Department from 2008. Previously, when a variable was shared across multiple data sources, scholars advised including only one effect size estimate for a single variable to prevent potential bias (Lipsey & Wilson, 2001). However, using this approach means limiting potential information by eliminating or reducing effect sizes (Cheung & Chan, 2004, 2008; Tanner et al., 2016). To overcome this problem, several scholars have recommended using multilevel modeling designed to address the issue of effect size dependence in nested data and allow inclusion of all studies and effects size estimates (Hox, 2010; Raudenbush & Bryk, 2002; Turanovic & Pratt, 2020). Using this statistical approach protects against biases introduced by dependent measures and increases total effect size estimates.

Because the sample of effect size estimates is nested within a three-level hierarchical structure (e.g., level 1 individual effect sizes, level 2 individual studies, level 3 individual datasets), I used multilevel modeling to treat the nested level data. Multilevel modeling uses the reliability of effect size estimates from the study and dataset levels, therefore more reliable effect size estimates from level 1 (e.g., study level) and level 2 (e.g., dataset level) are given greater weight in the analysis. In this way, the approach

prevents a study reporting 30 estimates from contributing 30 times more to an effect size estimate compared to a study reporting a single estimate (Van den Noortgate et al., 2013). This approach allowed me to include all effect size estimates and improve estimate precision. To complete this analysis, data were extracted from studies and entered an Excel spreadsheet. Data were organized by correlates that correspond to focal concerns (level 1), correlates that correspond to individual studies (level 2), and correlates that correspond to datasets (level 3). Once the data were constructed in this way, I used multilevel modeling to prevent unbalanced numbers of effect sizes per study and dataset from producing biased results (e.g., narrow confidence intervals, smaller standard errors, type one error) (Kreft and DeLeeuw, 1998). Additionally, rho, the user-specified within study effect correlation, was adjusted between 0 - 1 and unaffected the results, and thus the default value of rho was used.

Effect Size Estimates

Guided by established meta-analysis literature (see Berlin & Colditz, 1990; Brind et al., 1996; Cosgrove et al., 2003; Fleiss 1993; Fleiss & Berlin, 2009; Gaugler et al., 2007; Geddes & Lawrie, 1995; Greenland, 1987; Greenland, 1993; Haddock et al., 1998; Kochel et al., 2011; Lasky-Su et al., 2005; Lipsey & Wilson, 2001; Lösel & Schmucker, 2005; Mitchell, 2005; Tenback et al., 2009), logged odds ratios were used as the measure of effect size estimates. Logged odds ratios were selected for several reasons. First, because studies primarily used dichotomous outcomes, logged odds ratios were the most common measure used to study police and prosecutor decision-making. However, the inclusion of a dichotomous outcome was not an eligibility requirement. Second, most studies on police and prosecutor decision-making lacked sufficient

bivariate data to compare effect size estimates between bivariate and multivariate models. Third, logged odds ratios helped reduce potential spuriousness observed in bivariate results and to void overestimating effect size estimates. Fourth, if logged odds ratio values are not presented, formulas are available to transform other statistics into logged odds ratio estimates (e.g., probit coefficients and variances) (Hedges & Olkin, 1985). Fifth, logged odds ratio values are centered around zero, which makes it simple to interpret their strength and directionality (Hanushek & Jackson, 1977). Additionally, logged odds ratios can be transformed into odds ratios (i.e., also known as the natural anti-log or exponent B). Odds ratios (OR) are easily interpreted as the odds of an outcome occurring when exposed to an independent variable, compared to the odds of an outcome occurring without the exposure of the independent variable. For instance, $OR = 1$ independent variable generated no effect, $OR > 1$ independent variable correlated with higher odds of outcome, and $OR < 1$ correlated with lower odds of outcome (Szumilas, 2010).

Analytic Strategy

Recently, Turanovic and Pratt (2020) have argued for the field of criminal justice to reevaluate the criteria established for including and excluding studies, which “tends to result in narrowly focused meta-analyses” that fail to accurately represent existing literature (p. 3). The authors suggest traditional exclusion and inclusion criteria (*e.g., a priori*) force multiple meta-analyses to examine the same research questions, rather than produce a single meta-analysis that includes a full body of literature. This often means that scholars fail to compare different outcomes, even when the outcomes are similar. For instance, and most relevant to this review, researchers often exclude studies because their

outcome variables are seen as too different from each other (e.g., drug offenses vs. violent offenses). Following advice from Turanovic and Pratt (2020), this review conducted three separate multilevel models using random effects to be as inclusive as possible and produce results illustrative of existing evidence on the topic of case advancement in sexual assault cases. As such, model one conducted a meta-analysis that examined the correlates of police decisions to present a case for prosecutorial review and arrest, model two examines the correlates of prosecutor decisions to accept charges, and model three combined all decisions.

The first meta-analysis analyzed the effects of predictors on two police decisions, including the decision to make an arrest and the decision to present a case for prosecutorial review prior to making an arrest. Although these decisions points may appear to be different, both constitute a police decision to advance a case. For instance, Spohn and Tellis (2019) reported that police often have probable cause to make an arrest, however, some cases are rejected for prosecution when the officer presents a case for review before making an arrest. In such instances, no arrest occurs, and cases are often reported as exceptionally cleared because the prosecutor declined to accept charges. In addition, the decision to include both outcomes follows Turanovic and Pratt's (2020) recommendation to assess all studies included in a body of literature, even if the dependent variables are slightly different measures. The second meta-analysis analyzed correlates of prosecutorial decision-making. This meta-analysis examined only prosecutors and their decision to either accept or reject charges. The third meta-analysis used one model to examine police and prosecutor decision-making together. Doing so allows the review to assess overall correlates of case advancement from the arrest stage to

the charging stage. Meaning, the analysis is able to determine which correlates are most important to case progression across the arrest and prosecution stages. Combining the prosecutor and policing literature in this area allows this study to take stock in the applicability of focal concerns using the body of quantitative research on sexual assault decision-making.

Statistical Procedure

Multilevel modeling was used to conduct the main meta-analyses. In multilevel modeling, level 1 contains the effect size estimates, level 2 corresponds with individual studies, and level 3 corresponds with independent datasets (see Pratt et al., 2014; Wolfe & Lawson, 2020), which allows for every effect size across all studies to be analyzed rather than just a single effect size. The statistical procedure accounts for the possibility that effect sizes from a shared data source might be more similar than effect sizes from other studies (Raudenbush & Bryk, 2002). Additionally, as Turanovic and Pratt noted, “a study that reports 10 effect size estimates will not contribute to the meta-analysis 10 more than a study reporting 1 effect size” but that the procedure considers the reliability of within studies (Turanovic & Pratt, 2020, p. 12). Thus, greater weight are given to mean estimates from more reliable studies and less weight to less reliable studies. I used R’s *metafor* package to estimate random effects models with maximum likelihood estimation to assess all variance known multilevel models. In addition, the *Q*-statistic was used to assess heterogeneity of effect sizes estimates and moderating variables.

Publication Bias

Biases are often introduced into meta-analysis results because studies with statistically insignificant findings are less likely to be published than studies with

significant findings. To address issues of publication bias and “the file drawer problem” (Hunter & Schmidt, 2004), five procedures were used. First, publication bias was tested by funnel plot asymmetry (Begg & Mazumdar, 1994), and is based on the idea the plot of study effect sizes should be symmetric around the mean effect size estimate. Second, if asymmetry was detected, the trim-and-fill procedure (Duval & Tweedie, 2000) was used to impute missing studies. Third, Egger’s regression test was used to test for publication bias (Egger, 1997). Rosenthal’s classic fail-safe N test (Rosenthal, 1979) and Orwin’s fail-safe N test (Orwin, 1983). Fourth, fail-safe N tests were estimated to assess the number of potentially missing studies with nonsignificant results needed to increase the mean effect size above statistical significance $p < .05$ (Rosenthal, 1979). Fifth, Orwin’s fail-safe N test estimated the number of potential missing studies with null effects needed to reduce the mean effect for each variable to $OR = 1.00$. If tests produced large values, then the predictors are stable against publication bias (Hunter & Schmidt, 1990; Lipsey & Wilson, 2001). In addition, publication bias was assessed using results from two-level meta-analysis models, and should be interpreted with caution given the multilevel nature of the data. The Q -statistic is used to assess heterogeneity of effect sizes estimates and moderating variables.

Chapter Summary

The analytic strategy presented here was designed evaluate the strength and direction of correlates of police and prosecutor decision-making. The primary goals were to assess police officers’ decision to arrest and prosecutors’ decision to charge and examine the usefulness of the focal concerns perspective to explain these decisions. To attempt this goal, I used focal concerns measures offered by O’Neal and Spohn (2017)

and assessed the magnitude and direction of each variable on police and prosecutor decisions to advance cases. Additionally, a separate analysis combining both arrest and charging decisions was performed to estimate which case and victim characteristics are most important to case advancement.

These analyses were completed using multilevel modeling in the main analyses, which allowed me to include the maximum number of effect sizes and improve effect size estimate precision. In addition, I conducted sub-analyses using traditional meta-analysis techniques and addressed statistical effect size dependence by using effect size selection criteria and excluding specific dependent effect sizes. By completing the sub-analyses, I sought to compare traditional meta-analysis strategies suggested by Turanovic and Pratt (2020). Finally, to address issues of publication biases, funnel plots, trim-and-fill procedure, Egger's regression test of publication bias were used. In addition, Rosenthal's classic fail-safe N test (Rosenthal, 1979), and Orwin's fail-safe N test (Orwin, 1983) were used to examine the potential impact of publication bias on p-values and mean effect sizes.

CHAPTER 4

RESULTS

The goal of my dissertation was to explore five research questions about correlates of police and prosecutor decision-making in sexual assault cases and used three separate meta-analyses to answer these questions. The chapter presents results for arrest, charging, and both decision-making outcomes combined. The current chapter reports search results, study characteristics, meta-analysis results, forest plots, and analysis of publication bias.

Police Search Results

As shown in Figure 1, the search produced many potentially relevant studies for screening eligibility. The search located 1925 total unique studies, 35 potentially relevant studies after screening titles and abstracts, and 19 studies included in the review after full-text screening. As a result, the sample included 19 studies representing 222 effect sizes used in the meta-analysis. Several studies were eligible but excluded from the analysis because I was unable to accurately gather required statistical information. For instance, Lafree (1981) used weighted ordinary least squares, Brown et al. (2007) used Guttman-Lingoes' Smallest Space Analysis, and Snoodgrass et al. (2013) used an algorithmic model called Random Forest. In these studies I was unfortunately unable to locate an equation to accurately perform effect size transformations. In addition, Frazier and Haney (1996) and Morabito et al. (2019a) did not report standard errors or offer enough information was available to accurately calculate standard errors.

Figure 1. Search strategy and results for police studies.

Police Study Sample Characteristics

Table 4 lists 19 studies on police decision-making, including their sample size, data collection location, sample year(s), and whether the data source was shared with, or independent of, other studies. Of these studies, twelve were published after 2010, two were published between 2000-2010, and two were published before 2000. Sixteen studies were from peer-reviewed journals, two were dissertations (Campbell, 2015; Du Mont, 1999; Smith, 2005), and one was a final report from a National Institute of Justice funded study (Morabito et al., (2019b). Two studies (Du Mont, 1999; Scott & Beaman, 2004) occurred in Canada and the remaining took place in the United States. Two studies collected data from a rural location (Morabito et al., 2019b; Wood et al., 2011), and the remaining studies collected data from urban and/or suburban locations. Ten studies used independent data sources, and 9 analyzed shared data from the Los Angeles Police Department and Sheriff's Department (Kaiser et al., 2017; O'Neal et al., 2017; Spohn & Tellis, 2019), a large Midwestern police department (Alderden & Ullman, 2012a, 2012b), and a Midwestern police department (Wentz, 2019; Wentz & Keimig, 2019). Most studies include adolescents and adult victims in their sample, although four studies restricted their analyses to adult cases (Alderden & Ullman, 2012ab: Wentz, 2019; Wentz & Keimig, 2019) and the age of victims included in analyses was unspecified in three studies (Bouffard, 2000; Tasca et al., 2013; Ylang & Holtfreter). Finally, assessment of risk of bias indicated no potential risks or issues in study quality (see Appendix A).

Table 4. Police study characteristics

Study	N	Data location	Year	Data Source
Alderden & Ullman (2012a)	399	Large midwestern police department	2003	Shared
Alderden & Ullman (2012b)	328	Large midwestern police department	2003	Shared
Bouffard (2000)	326	Urban/Suburban	1995	Independent
Campbell (2015)	477	Houston PD	1986	Independent

Horney & Spohn (1996)	259	Detroit PD	1989	Shared
Kaiser et al. (2017)	770	LAPD/LASD	2008	Shared
Morabito et al. (2019b)	2732	Urban, suburban, & rural	2008-2010	Independent
O'Neal et al. (2019)	655	LAPD/LASD	2008	Shared
Scott & Beaman (2004)	87	Western Canada	1996	Independent
Smith (2005)	121	Maryland	2002-2003	Independent
Spohn & Tellis (2019)	491	LAPD/LASD	2008	Shared
Tasca et al. (2013)	115	Arizona City	2003	Independent
Venema et al. (2019)	22348	Midwestern police department	1999-20014	Independent
Wentz (2019)	231	Midwestern police department	2000-2010	Shared
Wentz & Keimig (2019)	418	Midwestern police department	2000-2010	Shared
Wood et al. (2011)	239	Alaska	2003-2004	Independent
Ylang & Holtfreter (2019)	310	LAPD/LASD	1982-2012	Independent

Police Meta-Analysis Results

Table 5 below displays the average effect size estimates organized by focal concerns concepts and their effect on arrest. Table 5 also provides the number of effect sizes for each variable, logged OR estimates, OR estimates, and 95% confidence intervals. For *suspect blameworthiness*, both victim resistance (OR = 1.10, $p > .05$) and victim injury (OR = 1.15, $p > .05$) had very small⁷ and nonsignificant effects on arrest. Results show when a victim physically or verbally resisted their attacker, the odds of arrest were 10% higher, and when the victim was injured, the odds of arrest were 15% higher. Offender weapon use (OR = 1.26, $p > .05$) was the only measure of *protection of the community* and was statistically insignificant. Cases involving a victim believed to be cooperating with the police investigation (OR = 5.90, $p < .001$) had the highest odds of arrest for *practical constraints* and was statistically significant. When a victim was believed to be cooperating in the investigation, odds of arrest increased by 490%. In addition, availability of physical evidence (OR = 1.72, $p < .05$) had a small effect on odds of arrest and was statistically significant. A prompt report of victimization to police (OR = 1.28, $p > .05$) had a very small effect on arrest and a witness(es) to the assault (OR = 1.16, $p > .05$) had a very small effect. Lastly, *perceptual shorthand* contained the most statistically significant variables. Victim substance use had a small effect (OR = .58, $p < .05$). When the victim reportedly used alcohol or other substances prior to the assault, the odds of arrest decreased by 42%. Victim credibility (OR = .62, $p < .05$) had a small and statistically significant effect on arrest, and when a report mentioned at least one variable

⁷ Effect sizes were described as very small, small, medium, and large using recommendations by Cohen (1988).

known to affect credibility, odds of arrest decreased by 38%. Cases involving non-strangers ($OR = 1.60, p > .05$) were 60% more likely to result in arrest, whereas cases involving intimate partners ($OR = 1.31, p > .05$) were 31% more likely to result in arrest. Suspect age ($OR = .80, p > .05$) and victim age ($OR = .78, p > .05$) had very small effects and were nonsignificant. While suspect race ($OR = .68, p > .05$) had a small effect and was nonsignificant. Similarly, victim race ($OR = .97, p > .05$) were statistically nonsignificant and had a very small effect.

Logged OR estimates for each predictor across studies were used to create a meta-regression plot (see Figure 2 below). Figure 2 displays the effects for arrest decision-making. The plot provide a visual representation of the odds surrounding each variable, which also includes effect size estimates, standard errors, significant level, and 95% confidence intervals. In the plot, points plotted to the right of zero indicate increased odds of arrest. These figures help visualize the overall magnitude and direction of each predictor. In addition, the precision of the estimates is shown by plotting the variables around 95% confidence intervals. Variables to the right of the solid line indicate a higher odds of arrest, while variables to the left of the solid line represent lower odds of arrest.

Figure 2. Meta-regression and log odds ratio for arrest.

Table 6 presents the average effect size estimate for each variable moderated by the sample year(s) of the study. Sample year was a continuous variable that was centered around its mean. This analysis sought to examine whether the sample year (i.e., the year the sexual assault was investigated) moderated effect size estimates. Results from the analysis show sample year ($p > .05$) was nonsignificant and effect size estimate remained unchanged.

Table 7 displays the average effect size estimates on arrest moderated by study sample size. The analysis included study sample size to determine if sample size moderated the effect size estimates. The study sample was dichotomized⁸ ($N > 350 = 1$) based on the sample mean across all police studies. Results from the analysis show study sample size ($p > .05$) was nonsignificant, meaning the effects were not moderated by study sample size. A final model including both sample year and sample size was analyzed, and results showed both study sample year ($p > .05$) and sample size ($p > .05$) did not moderate effect size estimates.

⁸ Two outlying samples were removed when calculating the overall mean, and allowed for more equal variation between smaller and larger samples. The same method was used for the prosecutor sample and the police and prosecutor combined sample.

Police Study Sample Publication Bias

To address the “file drawer problem” (Hunter & Schmidt, 2004), publication bias was assessed in five ways. First, publication bias was tested by funnel plot asymmetry (Begg & Mazumdar, 1994), and is based on the idea the plot of study effect sizes should be symmetric around the mean effect size estimate. Figure 3 shows the funnel plot for the police studies, and a visual inspection of the funnel plot indicated symmetry across effect sizes. Second, if asymmetry was detected, the trim-and-fill procedure (Duval & Tweedie, 2000) was used to impute missing studies. That said, there was no asymmetry, and the procedure imputed no studies. Third, Egger’s regression test was used to test for publication bias. Results from Egger’s regression test was nonsignificant ($z = 1.2665$, $p = .2053$) and indicated no clear evidence of publication bias. Fourth, Rosenthal’s classic fail-safe N test estimated the potentially missing studies with nonsignificant results needed to increase the mean effect size above statistical significance $p < .05$ (Rosenthal, 1979). Results were robust ($N = 27,787$) and would require many studies to increase p values above $p < .05$. Lastly, Orwin’s fail-safe N test estimated the number of potential missing studies with null effects needed to reduce the mean effect for each variable to $OR = 1.00$. Likewise, results were robust ($N = 6,810$) and would require many missing studies with null effects to substantially affect effect size estimates. Results from techniques assessing publication indicate the mean effect size estimates are protected against publication bias.

Figure 3. Funnel plot for arrest decision-making.

Prosecutor Search Results

Figure 4 below displays the results from the prosecutor search strategy. The search identified 1,508 total unique studies, 46 potentially relevant studies after screening titles and abstracts, and 20 studies were included in the analysis. In the end, 523 effect sizes were retained across 20 studies. Several studies were eligible but ultimately excluded from the analysis because I was unable to accurately gather required statistical information. Like the police sample, Lafree (1981) used weighted ordinary least squares, Brown et al. (2007) used Guttman-Lingoes' Smallest Space Analysis, and Kerstetter (1990) used Rao's *V* method. In these studies I was unfortunately unable to locate an equation to accurately perform effect size transformations to logit coefficients.

Figure 4. Search strategy and results for prosecutor studies.

Prosecutor Study Sample Characteristics

Table 8 below lists all 20 studies that examined prosecutor decision-making. Of these, ten were published after 2010, five were published between 2000-2010, and five were published before 2000. Eighteen studies were published in peer-reviewed journals, one was a final report from a National Institute of Justice funded study (Morabito et al., (2019b), and one study was a dissertation (Du Mont, 1999). As shown in Table 8, studies were primarily scattered across the United States and two studies collected data from Canada (Du Mont, 1999; Scott & Beaman, 2004). Two studies reported collecting data from a rural location (Morabito et al., 2019b; Wood et al., 2011), with the remaining largely collected from urban or suburban locations. Six studies used independent data sources and fourteen studies analyzed data collected from a combination of Miami, FL, Philadelphia, PA, and Kansas City, Mo (Beichner & Spohn, 2005; Beichner & Spohn, 2012; Holleran et al., 2010; Spohn and Holleran, 2001), Detroit police department (Horney & Spohn, 1996; Spears & Spohn, 1996; Spears & Spohn, 1997), Los Angeles police department and Sheriff's Department (O'Neal et al., 2017; Spohn & Tellis, 2019; St. George & Spohn, 2018), and a large Midwestern police department (Wentz, 2014; Wentz, 2019). Most studies included adolescent and adult victims in their sample, however, two included all ages (Spears & Spohn, 1996; Spears & Spohn, 1997) and one included only adults (Alderden & Ullman, 2012a). Finally, assessment of risk of bias indicated no potential risks or issues in study quality (see Appendix A).

Prosecutor Meta-Analysis Results

Table 9 below displays the average effect size estimates organized by focal concerns concepts and their effect on charging. For *suspect blameworthiness*, both victim resistance (OR = .89, $p > .05$) and victim injury (OR = 1.40, $p > .05$) were nonsignificant and had very small effects. For *protection of the community*, when the suspect used a weapon (OR= 1.23, $p > .05$), odds of charging increased by 23%. *Practical constraints* variables had the strongest effect on charging. Availability of physical evidence (OR = 1.75, $p > .05$) and prompt report (OR = 1.47, $p > .05$) were nonsignificant and had small effects on charging. Both victim cooperation (OR = .574, $p < .001$) had a large effect and the availability of a witness to the assault (OR = 2.19, $p > .05$) had a small effect and each were significant. When the victim was believed to be cooperating with practitioners, odds of charging increased by 474%, and when a witness was present, odds of charging increased by 119%. For *perceptual shorthand* variables, non-stranger relationships, (OR = .69, $p > .05$), intimate partner relationships (OR = .61, $p > .05$), suspect age (OR = .86, $p > .05$), victim age (OR = .83, $p > .05$), suspect race (OR = .71, $p > .05$), and victim race (OR = .99, $p > .05$) had very small effects on odds of charging and were nonsignificant. Non-stranger cases were 31% fewer odds of charging, intimate partner cases had 39% fewer odds of charging, and when the suspect was non-white, odds of charging decreased by 29%. Victim credibility (OR = .52, $p < .05$) had a small and significant effect on charging, and odds of arrest decreased by 48% when a report mentioned one variable that is known to affect credibility. Finally, if the victim used alcohol or drugs prior to the assault (OR = .52, $p > .05$), odds of charging decreased by 48%.

*Statistically significant at $p < .05$, ** statistically significant at $p < .01$, ***statistically significant at $p < .001$. *N* denotes the total number of effect size estimates. QE displays the test results for effect size heterogeneity, while QM displays the test results for moderator heterogeneity.

Logged OR estimates for each predictor across studies were used to create a meta-regression plot (see Figure 5 below). Figure 5 displays the plot for charge decision-making. The plot provides a visual representation of the odds surrounding each variable, which also includes effect size estimates, standard errors, significant level, and 95% confidence intervals. In the plot, points plotted to the right of zero indicate increased odds of charging. This figure help visualize the overall magnitude and direction of each predictor. In addition, the precision of the estimates is shown by plotting the variables around 95% confidence intervals. Variables to the right of the solid line indicate a higher odds of charging, while variables to the left of the solid line represent lower odds of charging.

Figure 5. Meta-regression plot and log odds ratio for charging.

Table 10 presents the average effect size estimate for each variable moderated by the sample year(s) of the study. Sample year was also used as a continuous variable that was centered around its mean. This analysis sought to examine whether the sample year (i.e., the year the sexual assault was investigated) moderated the effect sizes. Results from the analysis show sample year ($p > .05$) and effect size estimate remained unchanged.

Table 11 presents the average effect size estimates on charging moderated by study sample size. The study sample was dichotomized ($N > 300 = 1$) based on the sample mean across all prosecutor studies, which is why the variable is dichotomized differently than the police sample, and aimed to examine whether study sample had a moderating effect. Results showed study sample size ($p > .05$) was nonsignificant and results remained unchanged. Finally, the final model including both sample year and sample size was analyzed. Results showed both study sample year ($p > .05$) and sample size ($p > .05$) had no moderating effect.

Prosecutor Study Sample Publication Bias

The same five methods used to assess publication bias in the police sampler were used to assess publication bias within the prosecutor sample. First, publication bias was tested by funnel plot asymmetry (Begg & Mazumdar, 1994), and visual inspection of Figure 6 showed symmetry. Next, the trim-and-fill procedure was used and imputed effect sizes to the right of the mean, as shown in Figure 7. The adjusted model estimate after applying the trim-and-fill procedure was .3912. Imputed studies were likely the result of most credibility effect sizes being negatively correlated with arrest rather than publication bias. Third, Egger's regression test ($z = -.2028$, $p = .8393$) was nonsignificant and indicates no clear evidence of publication bias (Egger, 1997). Fourth, Rosenthal's classic fail-safe N test ($N = 6,471$) were robust and would require many studies for the mean effect size to become nonsignificant. Similarly, Orwin's fail-safe N test ($N = 5,177$) were robust and would require a sizeable number of missing effect sizes to nullify the mean effect. Tests for publication bias indicate the sample is procted against potential bias.

Figure 6. Funnel plot for charge decision-making.

Figure 7. Trim-and-fill procedure for charge decision-making.

Police and Prosecutor Meta-Analysis Results

Table 12 below displays the average effect size estimates organized by focal concerns concepts and their effect on case advancement – arrest and charging. For *suspect blameworthiness*, both victim resistance (OR = .97, $p > .05$) and victim injury (OR = 1.29, $p > .05$) were statistically insignificant and had very small effects on case advancement. When the victim was injured, the odds of case advancement were 29% higher. Offender weapon use (OR = 1.22, $p > .05$) was the only variable analyzed for *protection of the community* and had a very small and nonsignificant effect. Cases involving a victim believed to be cooperating with practitioners (OR = 5.81, $p < .001$) had the highest odds of advancement for *practical constraints* and was statistically significant. When a victim was believed to be cooperating in the investigation, odds of advancement increased by 481%. In addition, the availability of physical evidence (OR = 1.81, $p < .05$) had a small effect on case advancement and was statistically significant. When physical evidence was available, odds of case advancement increased by 81%. A prompt report of victimization to police (OR = 1.40, $p > .05$) was nonsignificant and increased odds of advancement by 40%. A witness(es) to the assault (OR = 1.81, $p < .01$) was statistically significant and had a small effect on advancement. For *perceptual shorthand*, victim credibility (OR = .55, $p < .01$) and victim substance use (OR = .53, $p < .01$) had the greatest effects on case advancement, and when a report mentioned at least one variable known to affect credibility, odds of case advancement decreased by 45%, and when the victim reportedly used alcohol or other substances prior to the assault, the odds of case advancement decreased by 47%. Both relationship types, non-stranger (OR = 1.02, $p > .05$) and intimate partner (OR = .94, $p > .05$) were nonsignificant and had

very small effects. Suspect age ($OR = .80, p > .05$), victim age ($OR = .81, p > .05$), suspect race ($OR = .70, p > .05$) were statistically nonsignificant and had very small effects on case advancement. Victim race ($OR = .97, p > .05$) was statistically nonsignificant and had a very small effect on case advancement.

Table 14 presents the average effect size estimates on charging moderated by study sample size. The analysis included study sample size to determine if larger samples affected the relationship between variables and case advancement. The study sample was dichotomized ($N > 325 = 1$) based on the sample mean across both police and prosecutor studies and aimed to examine whether study sample had a moderating effect. Results showed study sample size ($p > .05$) was nonsignificant, the effects were not moderated by study sample size, and smaller samples did not deviate significantly from larger samples. Finally, the model including both sample year and sample size was analyzed. Results showed both study sample year ($p > .05$) and sample size ($p > .05$) have no moderating effect.

Police and Prosecutor Study Sample Publication Bias

Five steps were used to assess publication bias within the combined police and prosecutor sample. First, publication bias was tested by funnel plot asymmetry (Begg & Mazumdar, 1994), and visual inspection of Figure 9 showed symmetry. Next, the trim-and-fill procedure was used and imputed several effect sizes. Figure 10 presents trim-and-fill procedure results. The adjusted model estimate after applying the trim-and-fill procedure was .4415. Imputed studies were likely the result of most credibility effect sizes being negatively correlated with arrest rather than publication bias.. Third, Egger's regression test ($z = -.3998$, $p = .6893$) was nonsignificant and indicates no clear evidence of publication bias. Fourth, Rosenthal's classic fail-safe N test ($N = 62,376$) were robust and would require many studies for the mean effect size to become nonsignificant. Similarly, Orwin's fail-safe N test ($N = 11,989$) were robust and would require a sizeable number of missing effect sizes to nullify the mean effect. Tests for publication bias indicate the sample was protected against potential bias.

Chapter Summary

This chapter presented results for three meta-analyses on practitioner decision-making in sexual assault cases. Most studies were published after 2000 in peer-reviewed journals, took place in the United States, used samples of adolescent/juvenile and adult victims, and often data collected in multiple jurisdictions. These meta-analyses estimated the magnitude and direction of focal concerns variables on practitioner decision-making, evaluated potential moderators, and assessed publication bias.

While some effects were consistent across each decision point (e.g., victim cooperation), the size of the effects and statistical significant varied at the arrest and charging stages. At arrest, availability of physical evidence, victim cooperation, and non-stranger assaults had the greatest effect on odds of arrest. In addition, questions about a victim's perceived credibility and substance use prior to the assault decreased odds of arrest. At charging, witness(es) to the assault and victim cooperation had the greatest effects on odds of charging and were statistically significant. Additionally, questions about a victim's perceived credibility decreased odds of charging and was statistically significant. For case advancement, availability of physical evidence, witness(es) to the assault, and victim cooperation had the greatest effects on odds of case advancement and were statistically significant. Additionally, questions about a victim's perceived credibility and substance use prior to the assault decreased odds of arrest and were statistically significant. Indeed, availability of physical evidence, victim cooperation, witness(es) to the assault, questions about a victim's perceived credibility, and substance use prior to the assault had the most consistent and robust effects on decision-making. Lastly, moderator analyses were conducted to assess whether sample year and sample

size potentially influenced the relationship between variables and outcomes. Moderator analyses results showed sample year and sample size did not moderate the relationships between predictors and outcomes.

To assess the potential problem of publication bias, funnel plots, the trim-and-fill procedure, Egger's regression test, and fail-safe *Ns* were performed to estimate potential bias. These procedures were used in the police sample, prosecutor sample, and the combined sample. First, in all three samples, results from Orwin's fail-safe *N* and Rosenthal's fail-safe *N* found all three samples robustly protected against potential publication bias and a substantial number of missing studies are required to meaningfully affect effect size estimates strength and significance. Second, Egger's regression tests were nonsignificant and detected no evidence of publication bias in all three samples. Third, while visual inspection of funnel plots revealed no evidence of publication in the police sample, visual examination of funnel plots for prosecutor and the combined sample revealed asymmetry and potential publication bias. As such, the trim-and-fill procedure was used to impute studies to create symmetry and visually display potentially missing studies, which was completed for both the police and combined sample. Visual inspection of the funnel plots and trim-and-fill procedure resulted in evidence of potential publication bias in the prosecutor and combined samples. This evidence of publication bias could be because of unpublished reports, studies missed during the search process, or study authors selectively publishing effects. Although Egger's regression test and fail-safe *Ns* indicated no publication bias within the samples, results should be interpreted with some caution.

CHAPTER 5

DISCUSSION

The focal concerns framework has been prevalent within the criminal justice decision-making literature for decades (Crow & Adrion, 2011; Hartley et al., 2007; Steffensmeier et al., 1998; Ulmer & Johnson, 2004). Additionally, the framework has been used to explain prosecutor, and more recently, police decision-making in sexual assault cases. That said, measurement inconsistencies of some victim and case characteristics have motivated scholars to apply more consistent measures to practitioner decisions in sexual assault cases. Research by O'Neal and Spohn (2017) proposed variables to operationalize focal concerns concepts, which could help reduce measurement inconsistencies and offer guidance to standardize measurement in future studies. Despite measurement differences across studies, many studies have used common correlates that fit with the focal concerns measures proposed by O'Neal and Spohn. Yet, no study has conducted a meta-analytic review to examine the magnitude and direction these variables have on practitioner decision-making. As a result, I sought to assess the applicability of focal concerns on decision-making in sexual assault cases and to evaluate the effects of focal concerns variables on decision-making, differentiate the key correlates of arrest and charging, and identify which correlates are most important to case advancement using meta-analysis.

The main goal of meta-analysis is to help estimate the size and direction of effect sizes across individual studies rather than determine statistical significance (see Haidich,

2010; Hedges & Olkin, 1980; Sullivan & Feinn, 2012). Thus, my goal was to summarize effect size estimates for correlates of arrest and charging and not focus primarily on statistical significance. To accomplish this, I adapted work by O'Neal and Spohn (2017) and expanded on their operationalization of focal concerns variables to assess how focal concern variables interact to affect practitioner decision-making. I classified common correlates of police and prosecutor decision-making into *suspect blameworthiness*, *protection of the community*, *practical constraints*, and *perceptual shorthand*. The study intended to evaluate these concepts, synthesize literature, and assess the empirical status of focal concerns as it relates to sexual assault cases and police and prosecutor discretion. Specifically, I aimed to contribute by (1) producing a systematic meta-analytic literature review of studies assessing correlates of police and prosecutor decision-making in sexual assault cases, (2) estimating the magnitude and direction of victim and case characteristics on decision-making, (3) examining whether the effects of victim and case characteristics differ between police and prosecutor decision-making, (4) combining police and prosecutor decision-making to determine which victim and case characteristics are most important to case advancement, and (5) assessing the applicability of focal concerns to understand case advancement among studies that examined both police and prosecutor decisions in sexual assault cases. To accomplish these goals, three primary meta-analyses were conducted. The first meta-analysis estimated effect sizes for arrest, the second estimated effect sizes for charging, and the third combined both decisions and examined case advancement. The analyses indicated overall empirical support for the focal concerns framework as applied to practitioner decision-making and many correlates robustly effected discretion at both stages.

Summary of Current Findings

At the arrest stage, the analysis produced robust effect sizes across many variables. First, *practical constraint* variables demonstrated the strongest effects. For instance, practical constraints contained two of the three strongest effect sizes. Victims believed to be cooperating during the investigation substantially and significantly increased odds of arrest by 490% and availability of physical evidence increased odds of arrest by 72%. These effects are likely because of the importance of physical evidence in identifying suspects and corroborating victim accounts of sexual assaults. In addition, a prompt report of victimization to police increased odds of arrest by 28% and witness(es) to the assault increased odds of arrest by 16% but were nonsignificant. Second, for *perceptual shorthand*, non-stranger assaults increased odds of arrest by 60% and was significant. Intimate partner assaults increased odds of arrest by 31% but was nonsignificant. This was unsurprising given the importance of identifying and locating suspects and the ability to readily identify suspects of intimate partner and non-stranger assaults (Spencer & Stith, 2020). Variables related to a victim's perceived credibility indicated a statistically significant 38% decrease in odds of arrest. In addition, victim substance use prior to the assault was significant and decreased odds of arrest by 42%. These findings were expected because police often ascribe to rape myths and have misconceptions about “true victims”, which involves victim behaviors prior, during, or after the assault (Estrich, 1987). Additionally, victim age decreased odds of arrest by 22%, suspect age decreased odds of arrest by 20%, non-White suspects decreased odds of arrest by 32%, and non-White victims decreased odds of arrest by 3%, but all were nonsignificant. When a suspect was non-white, odds of arrest decreased by 32% and is

opposite of the expected direction (Steffensmeier et al., 1998). However, research has found similar results when examining the way victim and suspect race/ethnicity interact and that the legal system's response will differ based on the victim/suspect/racial/ethnic dyad (Lafree, 1989; O'Neal et al., 2019). These studies argued that the legal system allocates fewer resources to cases involving minorities, which is supported by the current findings that cases involving non-White offenders and victims were less likely to result in arrest. Third, for *suspect blameworthiness*, victim resistance (e.g., verbal, physical, or both) increased odds of arrest by 10% and victim injury increased odds of arrest by 15%. Lastly, *protection of the community* was assessed using suspect weapon use, which increased odds of arrest by 26%.

At charging, *practical constraints* again had the greatest effect on decision-making. For instance, a victim believed to be cooperating increased odds of charging by 474% and witness(es) presence increased odds of charging by 119% and were both statistically significant. This corresponds with prior research (Kelley et al., 2021) and highlights the importance of victim testimony to determine probable cause. In addition, availability of physical evidence increased odds of charging by 75% and a prompt report of victimization increased odds of charging by 47%. *Perceptual shorthand* variables had the second greatest effects on charging. Non-stranger assaults decreased odds of charging by 31% and intimate partner assaults decreased charging by 39% and both were nonsignificant. These findings are also consistent with prior research that demonstrates practitioners believe "true victims" are assaulted by strangers (Estrich, 1987) and that cases are more likely to receive additional prosecutorial resources when the victim is a stranger (Bachman, 1998). Further, sexual assault cases that mentioned one variable

known to affect credibility significantly reduced odds of charging by 48%. Victim substance use prior to the assault also decreased odds of charging by 48%. These findings were expected given research has found practitioners often endorse rape myths, that misconceptions negatively impact decision-making, and that prosecutors focus on victim behaviors prior, during, and after the sexual assault (Estrich, 1987; O’Neal et al., 2019; Tellis & Spohn, 2008). Victim age decreased odds of charging by 17%, suspect age decreased odds of charging by 14%, and suspect race decreased odds charging by 29%. Like arrest, non-White suspects had 29% fewer odds of being charged, which is possibly due to fewer criminal-legal resources being allocated to cases involving non-Whites and practitioners may afford less effort when processing cases involving minorities (Kelley et al., 2021). In addition, victim race decreased odds of charging by 1%. For *suspect blameworthiness*, victim injury increased odds of charging by 40%. Victim resistance, however, affected charging in the opposite expected direction and decreased odds of charging by 11%. This is likely due to prosecutors relying on additional factors such as victim injury, witness(es), offender weapon use, and physical evidence when determining to accept a case. Lastly, the measure of the need for *protection of the community*, offender weapon use, increased the odds of charging by 23%.

The results for arrest and charging share similarities, however, some differences were detected in both the size and direction of effect sizes. First, *practical constraints* produced robust effects for both police and prosecutor decision-making. For instance, victim cooperation had a large effect on arrest and charging and increased arrest by 490% and charging by 474%. Similarly, the availability of physical evidence increased odds of arrest by 72% and charging by 75%. Still, the impact of witness(es) availability was

substantially different. Indeed, a witness(es) present increased arrest by 16% and charging by 119%. A prompt report of victimization increased the odds of arrest by 28% and increased the odds of charging by 47%. Greater differences were seen across outcomes regarding *perceptual shorthand*, specifically victim-offender relationship variables. Non-stranger assaults increased odds of arrest by 60%, whereas non-stranger assaults decreased odds of charging by 31%. Likewise, intimate partner assaults increased odds of arrest by 31% and decreased odds of charging by 39%. A victim's perceived credibility and substance use prior to the assault had similar effects on decision-making. When a victim's credibility was questioned, odds of arrest decreased 38% and odds of charging decreased 48%. Similarly, victim substance use prior to the assault decreased odds of arrest by 42% and decreased odds of charging by 48%. No differences in effects were found between arrest and charging for victim and suspect demographics, although suspect age, victim age, non-White suspects, and non-White victims were associated with decreased odds of arrest and charging. For *suspect blameworthiness*, the impact of victim resistance and victim injury were different across outcomes. For instance, victim resistance increased odds of arrest by 10% but decreased odds of charging by 11%. The effect of victim injury were stronger on charging. Specifically, victim injury increased the odds of arrest by just 15% but increased odds of charging by 40%. Finally, *protection of the community*, suspect weapon use increased odds of arrest by 26% and increased odds of charging by 23%.

The third analysis combined outcomes to explore the effects of variables on case advancement. Overall, *practical constraint* variables had the greatest effect on case advancement and odds a suspect would be arrested and charged. In fact, practical

constraints had the three most robust effect size estimates. Specifically, a victim believed to be cooperating increased odds of advancement by 481%, witness(es) presence increased odds of advancement by 81%, and availability of physical evidence increased odds of advancement by 81% and were each statistically significant. Additionally, a prompt report of victimization increased odds of advancement by 40%. Several *perceptual shorthand* variables had modest effects on case advancement. Of these variables, a victim's perceived credibility decreased odds of advancement by 45%, and substance use prior to the assault decreased odds of advancement by 47%. Indeed, results for victim credibility and substance alcohol use suggests practitioners are often influenced by rape stereotypes that reduce the odds of case advancement. Non-stranger stranger assaults increased odds of advancement by 2% and intimate partner assaults decreased odds of advancement by 6%. Victim age, suspect age, suspect race, and victim race each decreased odds of advancement. Cases with older victims decreased odds of advancement by 19%, cases with older suspects decreased odds of advancement by 20%, case involving non-White suspects had 30% fewer odds of case advancement, and cases involving non-White victims had 3% fewer odds of advancement. For *suspect blameworthiness*, victim injury increased case advancement by 29%, and victim resistance decreased advancement by 3%. Finally, for *protection of the community*, suspect weapon use increased case advancement by 22%. In sum, these results suggest focal concerns is a viable framework to explain police and prosecutor decision-making in sexual assault cases.

Policy Implications

Findings from these analyses highlight important avenues to inform policy and improve practitioner responses to victims of sexual assault. First, training is needed to improve practitioner (e.g., police, prosecutor) perceptions about victims and knowledge of victim trauma. Prior evaluations of police training have been shown to improve officer perceptions of victims and knowledge of victim trauma. For instance, research has shown training may effectively reduce attributions of blame towards victims (Darwinkel et al., 2013; Tidmarsh et al., 2020), reduce rape myth acceptance (B. Campbell et al., 2019; Murphy & Hine, 2019), and improve knowledge of trauma informed investigative techniques (B. Campbell et al., 2019; Franklin et al., 2019; Lonsway et al., 2001). In addition, training may help reduce officers' assessments of victim credibility and improve their knowledge about the usefulness of forensic evidence. This also suggests officers may rely on additional factors during the decision-making process and rely less on evaluations of victim credibility (B. Campbell et al., 2015). Moreover, I was unable to locate any prosecutor training evaluations on the topic of sexual assault. Based on findings from my meta-analytic review, prosecutors rely equally on evaluations of victim credibility and extralegal variables during the decision-making process. Police training evaluations have detected positive improvements among police samples across several outcomes, and it is reasonable to hypothesize prosecutors may equally benefit from attending sexual assault training courses. Thus, findings suggest training may be an effective means to advance police sexual assault training and to encourage future researchers to design, implement, and evaluate prosecutor training on sexual assault. Specifically, there are four primary ways to enhance training.

First, victim cooperation expressed the greatest effect on decision-making across all models. Thus, training should be aimed at facilitating and maintaining victim cooperation throughout the legal process. Sexual assault training programs should include educating practitioners on victim-centered and trauma-informed techniques throughout investigation and prosecution, specifically when conducting initial and follow-up interviews. Applying victim-centered and trauma-informed techniques may reduce instances of secondary trauma and improve victim engagement (see B. Campbell et al., 2020; Tidmarsh et al., 2020).

Second, availability of physical evidence substantially affects each decision-making stage, which stresses the importance practitioners place on physical evidence during the decision-making process. Thus, practitioners should be offered training about the collection and processing of physical evidence at crime scenes and enhancing the utility of forensic evidence. Training officers on how to properly collect and process evidence may help establish probable cause to arrest and secure evidence helpful for prosecution. Additionally, training curriculums could incorporate information on sexual assault kits and stress the benefits of collecting and testing kits. Indeed, recent work has demonstrated the importance of sexual assault kit processing as a useful tool for practitioners. The recent push to process sexual assault kits has also established links between offenders to multiple unsolved sexual assaults. These offenders not only commit sexual violence but other various violent and property crimes after eluding arrest and prosecution. Lovell et al. (2020) analyzed cases of previously untested sexual assault kits and found undetected offenders commit future felonies. In fact, Lovell and colleagues (2020) found offenders commit an average of 7.4 felonies before being apprehended for

their latest sexual offense. That said, educating practitioners about the significance of processing physical evidence and sexual assault kits could reduce sexual offenses as well as prevent future property and violent crimes.

Third, and more importantly, training should also focus on improving the likelihood of making an arrest and charging when physical evidence is unavailable in a sexual assault case. When physical evidence is not available, practitioners have often relied on victim credibility attributes and rape myths to make decisions about which cases do – and do not – move forward (B. Campbell et al., 2015). However, research has pushed for training focusing on overcoming consent defenses put forth by suspects, and documenting how trauma affects victims' emotional and cognitive reactions to sexual assault (R. Campbell et al., 2012). Both aspects of training can assist in corroborating victim allegations and educating jurors about the dangers of relying on rape myths when making decisions in sexual assault cases.

Fourth, evaluations of victim credibility and substance use prior to the assault greatly decreased case advancement, and provided evidence rape myths impact arrest and charging decisions across studies. Additional training is necessary to educate practitioners on rape myths and dispel misconceptions about sexual assault cases and victims. For instance, my analysis indicated victim injury, suspect weapon use, victim credibility, and victim substance use prior to the assault impact arrest and charging decisions. Thus, training practitioners about rape myths may improve their knowledge of sexual assault cases and victims and help reduce victim-blaming and reliance on an assessment of victim credibility when making decisions to advance cases. A recent statewide training in Kentucky implemented these recommendations in a comprehensive

40-hr sexual assault training course, which covered rape myth acceptance, the use of physical evidence in investigations, dynamics of sexual assault, trauma-informed investigations, and victim interviews. An evaluation of this training revealed positive short-term and long-term improvements in knowledge of trauma-informed practices, knowledge of Kentucky laws, and perceptions of victims (B. Campbell et al., 2020). Creating and implementing similar training programs for prosecutors could be beneficial in improving prosecutors' perceptions of victims and knowledge of trauma informed responses.

Limitations

Though this study provides several contributions to the literature, there are a few limitations worth noting. First, some studies might have been missed during the search strategy. In addition, publication bias was potentially detected in the prosecutor and combined samples, however the imputed effect sizes were likely the result of most credibility effect sizes being negatively correlated with arrest rather than publication bias. Further, these tools assessed bias using results from two-level meta-analysis models, and should be interpreted with caution given the multilevel nature of the data. That said, future meta-analysis should widen searches to include additional databases, specifically databases that include studies from other fields closely related criminal justice. Publication bias may also be addressed by scholars publishing results regardless of effect size statistical significance, strength, and direction of the relationship between key independent variables and outcome measures.

Second, some information was unavailable to assess certain moderators, such as the racial composition of both victims and suspects in some studies. Future studies should

report demographic information so that future meta-analyses may assess the role of racial composition as a moderating variable. That said, in this study, supplemental moderator analyses did suggest uniformity across studies. Meaning, the sample year(s) and sample size had no moderating effects. Further, not enough studies reported effect sizes to evaluate the impact of physical assault on arrest and charging decisions, as suggested by O'Neal & Spohn (2017). Thus, suspect weapon use was the only variable analyzed that measured protection of the community. When this physical assault is available to scholars, future meta-analyses could include it in their analyses.

Future Research Directions

To advance this line of research and address these limitations, future meta-analyses should examine additional decision-making outcomes. The decision to unfound has been studied by Ferguson & Malouff (2016) using meta-analysis, however, other outcomes such as the ability of police to identify a suspect, the decision to interview a suspect, and practitioner judgements about victim cooperation during the investigative and prosecutorial processes warrant future evaluations. Exploring these decisions will help better understand multiple practitioner decision points in the process, as well as help understand factors that reduce victim engagement. Using meta-analysis to examine studies on victim cooperation may help identify factors impacting victim engagement and offer ways police training can target such factors and focus on methods known to facilitate victim engagement. Second, future research should reduce effect size heterogeneity by using uniform measures. This can be accomplished by following O'Neal and Spohn's (2017) operationalization of focal concerns variables and the measures that were presented in this study. In this way, measures across studies can be standardized and

can improve study replication and generalizability. Following these recommendations for the operationalization of variables can also increase the accuracy of effect size estimates, and improve our understanding of the association between focal concerns variables and practitioner decision-making in sexual assault cases.

Despite the minor limitations mentioned above, this meta-analytic significantly contributes to the literature by examining correlates of case advancement at multiple decision-making stages and assessing the applicability of focal concerns to explain practitioner discretion in sexual assault cases across studies. Thus, my findings identified the strongest correlates of practitioner decision-making and found empirical support for the application of the focal concerns framework in sexual assault cases. Variables for each focal concerns concept had sizeable effects on decision-making, however not all were statistically significant. Finally, moderator analyses using sample year and sample size did not significantly influence the relationship between focal concerns variables and arrest and charging decisions.

A future meta-analysis should take additional steps to assess moderating effects of focal concerns variables. First, an overall model without moderating variables. Second, a series of meta-regression models using a single moderator per model. Third, subgroup analyses using effect sizes for each focal concerns concept. In this way, scholars can capture whether effect sizes from specific focal concerns variables are significantly different and isolate the effects for each concept.

GRANTS

Grant Experience

2018-Present

Research Assistant

An Evaluation of Victim Centered, Trauma Informed Interview Training for Sexual Assault Investigators using Standardized Patient Actors: A Randomized Controlled Trial. Funded by the National Institute of Justice 2018 Research and Evaluation on Violence Against Women (\$335,13).

Supervisor: Bradley A. Campbell, Ph.D. and Rachel Carter, M.F.A.

Duties: Coding interviews, survey development, survey administration, data collection (audio, video, survey), data management in the field, and experiment implementation.

2017 – 2020

Project Manager:

Kentucky Office of the Attorney General Sexual Assault Kit Initiative (SAKI) Purpose Area 1. Funded by the Bureau of Justice Statistics FY 17 National Sexual Assault Kit Initiative: Comprehensive Approach to Untested Sexual Assault Kits (Total: \$2,998,090; University of Louisville subcontract: 189,831). Supervisor: Bradley A. Campbell, Ph.D.

Duties: Survey development, survey administration, data entry, merging secondary data with original data, data management, data analysis, technical report writing, and presenting findings to practitioners.

January 2017 – September 2017

Research Assistant:

Sexual Assault Forensic Examination (SAFE) Kit Backlog Research Project: A Statewide Evaluation of Sexual Assault Kit Testing Results, Submission Rates, Case Outcomes, and the Impact of SB 63 on Investigations in Kentucky. Funded by the Kentucky Office of the Attorney General, Office of Victims Advocacy (University of Louisville Award Total: \$49,998.00).

Supervisor: Bradley A. Campbell, Ph.D.

Duties: Survey development, merging secondary data with original data, data entry, data management, technical report writing, and presenting findings to practitioners.

Grant Awarded

2016 **Lapsey Jr., D.S. (PI)**, Campbell, B.A. (Faculty Supervisor) Louisville Metro Police Department Homicide Investigation Project. University of Louisville, Graduate Student Thesis Grants for Research and Creative Activities in the College of Arts and Sciences (\$811.00).

TECHNICAL REPORTS

2018 Campbell, B. A., & Lapsey, D. S. SAFE kit submission to the KSP Forensic Laboratory: An analysis of trends before and after DANY/SB63. Solicited report for the Kentucky SAFE Kit Backlog Research Project Working Group (15 pages).

2018 Campbell, B. A., & **Lapsey Jr., D.S.** An evaluation of the Kentucky DOCJT Sexual Assault Investigator Training Program: Results from a Solomon four-group design. Solicited report for the Kentucky SAFE Kit Backlog Research Project Working Group (30 pages).

2018 **Lapsey Jr., D.S.**, Simpkins, B., Braden, V. Louisville Metro Police Department Real

Crime Center: Evaluation and Recommendations. Solicited Presentation to Louisville Metro Police Real Time Crime Center and Louisville Metro Police Department (28 pages).

- 2018 **Lapsey, D. S.,** & Campbell, B. A. Kentucky sexual assault responder training: Results and recommendations from DOCJT and KY OAG trainings. Solicited report prepared for the Kentucky SAFE Kit Backlog Working Group (14 pages).
- 2018 Campbell, B.A., & **Lapsey Jr., D.S.** Post CODIS-hit victim engagement: Review of the literature and data collection recommendations. Solicited report prepared for the Kentucky SAFE Kit Backlog Working Group (12 pages).
- 2017 Campbell, B.A., & **Lapsey Jr., D.S.** LMPD SVU Preliminary Results from DANY Untested Cases and Notification Efforts: Analysis of LMPD and KSP Lab Data up to December 5, 2017 (19 pages).

CONFERENCE PRESENTATIONS

- 2019 Campbell, B.A. & **Lapsey Jr., D.S.** The impact of self-control and training on police perceptions of victims: Results from a partially randomized experiment. American Society of Criminology. San Francisco, CA. November.
- 2019 **Lapsey Jr., D.S.** & Campbell, B. A. What caused the backlog? Correlates of the decision to submit sexual assault kits for forensic analysis in Kentucky. American Society of Criminology. San Francisco, CA. November.
- 2019 **Lapsey Jr., D. S.** & Campbell, B. A. Impact of training, impulsivity, and charge perceptions on decisions in hypothetical sexual assault cases: Evidence from a randomized study. Midwestern Criminal Justice Association: Chicago, IL. September.
- 2018 Overstreet, S., McNeely, S., & **Lapsey Jr., D.S.** Can victim, offender, and situational characteristics differentiate between lethal and non-lethal intimate partner violence? American Society of Criminology: Atlanta, GA. November.
- 2018 **Lapsey Jr., D. S.** & Campbell, B. A. The impact of statewide reform on the submission and testing of sexual assault kits. American Society of Criminology: Atlanta, GA. November.
- 2018 Campbell, B. A. & **Lapsey Jr., D. S.** An evaluation of statewide sexual assault investigator training: Results from a Solomon four-group design. American Society of Criminology: Atlanta, GA. November.
- 2017 Campbell, B.A. & **Lapsey Jr., D.S.** Cold case training—from investigation to convictions: Prosecuting sexual assault cold cases. Lexington, KY. June.

2016 **Lapsey Jr., D.S.** Colombian law enforcement Conference: Managing media and police relations: Louisville, KY. April.

INVITED PRESENTATIONS

2019 **Lapsey Jr., D.S.** & Aldridge, C. Strategies for Success and Sustainability. Solicited Presentation to the 4th Annual National Sexual Assault Kit Initiative (SAKI) Grantees Meeting, Arlington, VA. June.

2018 **Lapsey Jr., D.S.**, Simpkins, B., & Braden, V. Louisville Metro Police Department Real Time Crime Center: Evaluation and Recommendations. Solicited Presentation to Louisville Metro Police Real Time Crime Center and Louisville Metro Police Department, Louisville, KY. April.

2018 Program Evaluation of the Living Room Program. Solicited Presentation to Louisville Metro Police Department, Louisville Department of Corrections, and Centerstone Mental Health Services, Louisville, KY. April.

2017 Campbell, B.A. & **Lapsey Jr., D.S.** Kentucky SAFE Kit Backlog Research Project: SART-AC Research Update on Preliminary Findings. Solicited Presentation to the Kentucky Sexual Assault Response Team Advisory Committee, Frankfort, KY. October.

TEACHING

Undergraduate Course Taught (University of Louisville)
Police and the Community (Fall, 2019)

Undergraduate Course Prepped (University of Louisville)
Police in the United States

PROFESSIONAL DEVELOPMENT

Bureau of Justice Assistance's Researcher Practitioner Partnerships Fellows Academy (40 hours). February 2018.

Federal Bureau of Investigation's ViCAP Kentucky Regional Training (16 hours). June 2019.

Forensic Interview Trauma Interview (FETI) Kentucky Regional Training (8 hours). May 2018.

PROFESIONAL ORGANIZATION SERVICES

- 2019 *Registration Table for the Midwestern Criminal Justice Association (MCJA)* – Chicago, IL (University of Louisville).
- 2018 *Registration Table for the Midwestern Criminal Justice Association (MCJA)* – Chicago, IL (University of Louisville).
